Basic Tasks Intervals Might Accomplish

Account for uncertainty in measurements What range of outputs is expected from a range of inputs?

Account for roundoff error with mathematical rigor
Provide numerical output with the certainty of a mathematical proof.

Compute bounds on ranges Lower bounds and upper bounds on quantities might be computed easily.

Handle multiple-valued quantities simply This includes direct computation with generalized gradients of non-smooth functions.

Early Motivations for Interval Arithmetic

Prior to the Age of Digital Computation

The same basic interval operations were described in all of these works, but with somewhat different motivations. All of this early work is apparently independent.

Rosaline Cecily Young (*Mathematische Annalen*, 1931)

“The Algebra of Many-Valued Quantities.”

The focus is on an arithmetic on limits, where $\liminf_{x \rightarrow x_0} f(x)$ and $\limsup_{x \rightarrow x_0} f(x)$ are distinct¹. Describing ranges and encompassing roundoff error does not seem to have been the primary motivation.

¹Such limits might occur in generalized gradients of non-smooth functions.

What Have I Forgotten?

Paul S. Dwyer (Chapter in *Linear Computations*, 1951)

“Computation with Approximate Numbers.”

Interval computations are introduced as an integral part of roundoff error analysis.

Mieczyslaw Warmus (*Calculus of Approximations*, 1956)

“Calculus of Approximations.” The

motivation is apparently to provide a sound theoretical backing to numerical computation.

Teruro Sunaga (*RAAG Memoirs*, 1958) “Theory of an Interval Algebra and its Application to Numerical Analysis.” The emphasis is on mathematical theory, but the motivation appears to be automatically accounting for uncertainty and error in measurement and computation.

(slide 13)

Early Motivations for Interval Arithmetic

From the Onset of the Age of Digital Computers
(continued)

Ray Moore (*Lockheed Technical Report*, 1959)
“Automatic Error Analysis in Digital Computation.” The motivation is given in the title. The basic operations are given in this monograph, and development of numerical solution of ODE’s, numerical integration, etc. based on intervals is in Moore’s 1962 dissertation. It is made clear that interval computations promise rigorous bounds on the exact result, even when finite (rounded) computer arithmetic is used.

References are from the interval computations website, at <http://www.cs.utep.edu/interval-comp>

The Basic Operations of Interval Arithmetic

(slide 14)

- Each basic interval operation $\odot \in \{+, -, \times, \div, \text{etc.}\}$ is defined by

$$\mathbf{x} \odot \mathbf{y} = \{\mathbf{x} \odot \mathbf{y} \mid \mathbf{x} \in \mathbf{x} \text{ and } \mathbf{y} \in \mathbf{y}\}.$$

- This definition can be made operational; for example, for $\mathbf{x} = [\underline{x}, \bar{x}]$ and $\mathbf{y} = [\underline{y}, \bar{y}]$, $\mathbf{x} + \mathbf{y} = [\underline{x} + \underline{y}, \bar{x} + \bar{y}]$; similarly, ranges of functions such as \sin , \exp can be computed.
- Evaluation of an expression with this interval arithmetic gives *bounds* on the range of the expression.
- With *directed rounding* (e.g. using IEEE standard arithmetic), the computer can give mathematically rigorous bounds on ranges.

Interval Operations

Advantages

- Computing sharp bounds on ranges is an NP-hard problem.
- Computing range bounds with interval computations is quick and simple.
- The range bounds get sharper asymptotically as the widths of the domain intervals tend to zero, and, with *second-order extensions*, will do so rapidly.

(slide 19)

Interval Operations

Pitfalls

- The interval values contain the actual ranges, but are possibly significantly larger. For example, if $f(x) = (x + 1)(x - 1)$, then

$$\begin{aligned}f([-2, 2]) &= ([-2, 2] + 1)([-2, 2] - 1) \\ &= [-1, 3][-3, 1] = [-9, 3],\end{aligned}$$

whereas the exact range is $[-1, 3]$.

- However, if we write f equivalently as $f(x) = x^2 - 1$, and we suppose we compute the range of x^2 exactly, we obtain

$$f([-2, 2]) = [-2, 2]^2 - 1 = [0, 4] - 1 = [-1, 3],$$

the exact range.

$$f([-2, 2]) = [-2, 2]^2 - 1 = [0, 4] - 1 = [-1, 3],$$

the exact range.

(slide 23)

Dependency and Overestimation

Consequences

- This range overestimation above is caused by the arithmetic not taking account of the fact that, when $x = 2$ in $(x + 1)$, x must also equal 2 in $(x - 1)$.
- This phenomenon is at the root of many failures of interval arithmetic.
- For this reason, interval arithmetic should be used with skill, only in appropriate places.
- Naively converting a floating point code to interval computation by simply changing the data types is far more likely to fail than succeed.
- However, there are some notable successes.

Fast Bounds on Ranges

A *Filter* in Branch and Bound Methods

(slide 29)

- In branch and bound methods for global optimization, methods are needed for rejecting regions \mathbf{x} that cannot contain global optimizing points.
- \mathbf{x} can contain a global optimizing point only if
 - It contains points x that satisfy constraints $c_i(x) = 0$ and $g_j(x) \leq 0$.
 - It contains points x such that the quantity φ to be optimized obeys $\varphi(x) \leq \bar{\varphi}$, where $\bar{\varphi}$ is a previously computed upper bound on the global optimum value.
- Regions \mathbf{x} can sometimes be quickly eliminated by evaluating φ , the c_i , and the g_j and checking violation of the conditions. For example, if the lower bound on one of the $g_j(\mathbf{x})$ is greater than 0, then \mathbf{x} may be eliminated from further consideration.
- This technique is widely acknowledged in the general literature and used in leading commercial software.

Promise

Some PDE Problems

Unusual Uses of Intervals

What Have I
Forgotten?

(slide 35)

Use in Branch and Bound Methods

Constraint Propagation

- This is based on a simple idea: Solve a relation in many variables for one of the variables, then plug in bounds on the other constraints to compute new bounds on the original constraint.
- The technique is the foundation of an entire field, with expertise at UTEP (Martine Ceberio).
- The technique is incorporated into leading commercial global optimization software (BARON).

Some PDE Problems

Unusual Uses of Intervals

What Have I
Forgotten?

Constraint Propagation

A Simple Illustrative Example

(slide 36)

Consider

$$\begin{aligned} &\text{minimize } \varphi(x) = x_1^2 - x_2^2 \\ &\text{subject to } x_1^2 + x_2^2 = 1, \\ &\quad \quad \quad x_1 + x_2 \leq 0. \end{aligned}$$

- Suppose we have already found the feasible point $\hat{x} = (0, -1)$ with $\varphi(\hat{x}) = -1$, so -1 is an upper bound on the optimum.
- Suppose we are searching in the box $([-1, 1], [-1, 1])$.
- Using the upper bound $\bar{\varphi}$ gives

$$x_1^2 - x_2^2 \leq -1.$$

- Solving this for x_1 gives \dots

- Using the upper bound $\bar{\varphi}$ gives

$$x_1^2 - x_2^2 \leq -1.$$

- Solving this for x_1 gives ...

Constraint Propagation

A Simple Illustrative Example

(slide 39)

Consider

$$\begin{aligned} &\text{minimize } \varphi(x) = x_1^2 - x_2^2 \\ &\text{subject to } x_1^2 + x_2^2 = 1, \\ &\quad \quad \quad x_1 + x_2 \leq 0. \end{aligned}$$

- Suppose we have already found the feasible point $\hat{x} = (0, -1)$ with $\varphi(\hat{x}) = -1$, so -1 is an upper bound on the optimum.
- Suppose we are searching in the box $([-1, 1], [-1, 1])$.
- Using the upper bound $\bar{\varphi}$ gives

$$x_1^2 - x_2^2 \leq -1.$$

- Solving this for x_1 gives \dots

Constraint Propagation

(Simple Example, Continued)

(slide 40)

- (solving for x_1 in the objective condition)

$$x_1 \leq \sqrt{[-1, 1]^2 - 1} = \sqrt{[0, 1] - 1} = \sqrt{[-1, 0]}$$

and

$$x_1 \geq \sqrt{[-1, 1]^2 - 1} = \sqrt{[0, 1] - 1} = \sqrt{[-1, 0]}.$$

- Here, it is appropriate to interpret $\sqrt{[-1, 0]} = 0$, so we obtain $x_1 = 0$.
- We now solve for x_2 in $x_1^2 + x_2^2 = 1$ and plug in $x_1 = 0$ to get

$$x_2 = 1 \quad \text{or} \quad x_2 = -1,$$

- Plugging $x_1 = 0, x_2 = 1$ into $x_1 + x_2 \leq 0$ gives a contradiction, leading to the unique point $x = (0, -1)$ in $([-1, 1], [-1, 1])$ that can be a global optimizer.

COSY Infinity and Taylor Arithmetic

(slide 45)

- Martin Berz and Kyoko Makino have included these methods in the *COSY Infinity* software for modeling beams in particle accelerators. This software is used by thousands of beam theorists worldwide.
- The techniques have been used to predict
 - Bounds on orbits of near-Earth objects (proving they will not hit the Earth),
 - Bounds on paths of particles in actual and planned particle accelerators (proving feasibility before expensive accelerators are built).
- Berz and Makino are recipients of this year's Moore Prize (presentation to be given 1:15–2:00 today).

Unusual Uses of Intervals

What Have I
Forgotten?

3D Photonic Crystals Michael Plum will give a plenary lecture on “A Computer-Assisted Band-Gap Proof for 3D Photonic Crystals” on Thursday at 9:45 AM.

Other PDE applications Hashimoto, Kimura, Kinoshita, Nakao, Nagatou, Tomura, Watanabe, and Yamamoto present papers on rigorous error bounding in elliptic and other PDEs, in an “Applications to PDEs” session on Tuesday at 11:00.

Various PDE Problems

(slide 70)

The Promise of
Interval Arithmetic

Things it Might Do

Early Motivations

How Does Interval
Arithmetic Work?

Advantages and
Pitfalls

Areas Currently
Impacted

Nonlinear Programming

Verified ODE's

Automatic Theorem Proving

General Numerical Work

Chemical Engineering

Areas With Strong
Promise

Some PDE Problems

Unusual Uses of Intervals

Unusual Uses of Intervals

What Have I
Forgotten?

- See the session on “Applications to Decision Making and Finance” on Tuesday at 3:40.
- Chenyi Hu and Ling T. He have proposed a singular value analysis based on interval matrices that compares favorably to existing methods for modeling stock market indices. However, the idea is not related to rigorous enclosure of errors.

Unusual Uses of Intervals

What Have I
Forgotten?

- Is there some important application I have failed to mention?
- Are some of the things I have listed as “promising” actually *faites accomplis*?
