1. Main Problem: Introduction

- *One of the main objectives of physics:* predict the future behavior of real-world systems.
- *Fact:* in modern physics, models for space, time, causality, and physical processes in general are very complex.
- *Example:*
 - *physical phenomenon:* a simple space-time;
 - *formalism:* quantum physics;
 - *mathematical description:* a wave function $\psi(M)$ defined on all pseudo-Riemannian manifolds M .
- *Corollary:* prediction-related computations are often extremely time-consuming.
- *Sometimes:* by the time we finish prediction computations, the predicted event has already occurred.
- *Problem:* how can we speed up these computations?

2. An Approach to Solving the Main Problem: Operationalism

- *Fact*: in modern physics, many quantities used in the corresponding equations are not directly observable.
- *Example*: the wave function $\psi(x)$.
- *Related idea*: restrict ourselves to only computing directly observable quantities.
- *Hope*: by not computing other quantities, we can save computation time.
- *Reason for this hope*: a similar operationalistic approach has been very successful in physics:
 - *special relativity*: started with Einstein's analysis of simultaneity;
 - *general relativity*: Einstein's equivalence principle;
 - *equations of quantum physics*: Heisenberg's matrix equations (motivated by operationalism).

3. Towards Operationalistic Approach to Computational Physics: Binary Domains

- *General idea:* in any real-life measurement, we have a finite set X of possible measurement results.
- *Description of measurement uncertainty:* $a \sim b \leftrightarrow$ the same object can lead to both a and b .
- *Physical example:* temperature t° ; values $0, 1, \dots, 100$; *measurement accuracy:* $\pm 0.5^\circ$.
- $X = \{0, 1, 2, 3, \dots, 100\}$; $a \sim b \leftrightarrow |a - b| \leq 1$.

$\times - \times - \times - \dots - \times - \dots - \times - \times - \times$

- *Modified example:* measurement accuracy $\pm 1^\circ$.
- $X = \{0, 1, 2, 3, \dots, 100\}$; $a \sim b \leftrightarrow |a - b| \leq 2$.

$\times - \times - \times - \dots - \times - \dots - \times - \times - \times$

4. Towards Operationalistic Approach to Computational Physics: Binary Domains (continued)

- Counting up to n : $X = \{1, 2, \dots, n-1, \text{many}\}$:

$$0 \quad 1 \quad \dots \quad k \quad \dots \quad (n-1) \quad \text{many}$$

- Binary questions: “yes” (1), “no” (0), “unknown” (U);
 $X = \{0, 1, U\}$, $0 \sim U \sim 1$.

$$0 \text{-----} U \text{-----} 1$$

- Repeated “yes”-“no” measurements: 5 possible outcomes: 0_1 , 1_1 , $U_1 0_2$, $U_1 1_2$, and $U_1 U_2$.

- If the actual value is 0, we can get 0_1 , $U_1 0_2$, $U_1 U_2$;
- if the actual value is 1, we can get 1_1 , $U_1 1_2$, $U_1 U_2$.

$$\begin{array}{ccccccc} & & \diagup & & \diagdown & & \\ 0_1 & \text{-----} & U_1 0_2 & \text{-----} & U_1 U_2 & \text{-----} & U_1 1_2 & \text{-----} & 1_1 \\ & & \diagdown & & \diagup & & \end{array}$$

- General case: graph (web) $\langle X, \sim \rangle$.

5. A More Adequate Description: Simplicial Complexes

- *Previously:* we only considered compatibility of pairs of measurement results.
- *Natural idea:* consider compatibility of triples, etc.
- *Formalization:*
 - a set $S \subseteq X$ is *compatible*
 - if for some object, all values from S are possible after measurement.
- *Simplicial complex:* a pair $\langle X, \mathcal{S} \rangle$, where $X \subseteq \mathcal{S} \subseteq 2^X$ is the class of all compatible sets.

6. Simplicial Complex: Example 1

- *Example 1:* $X_i \cap X_j \neq \emptyset$ but $X_1 \cap X_2 \cap X_3 = \emptyset$.
- *Corresponding simplicial complex:* empty triangle
 - $X = \{x_1, x_2, x_3\}$,
 - $\mathcal{S} = \{\{x_1\}, \{x_2\}, \{x_3\}, \{x_1, x_2\}, \{x_2, x_3\}, \{x_1, x_3\}\}$.
- *Illustration:*

7. Simplicial Complex: Example 2

- *Example 2:* $X_1 \cap X_2 \cap X_3 \neq \emptyset$.

- *Corresponding simplicial complex:* filled triangle

$$X = \{x_1, x_2, x_3\},$$

$$\mathcal{S} = \{\{x_1\}, \{x_2\}, \{x_3\}, \{x_1, x_2\}, \{x_2, x_3\}, \{x_1, x_3\}, \{x_1, x_2, x_3\}\}.$$

8. How to Describe Actual Values of Measured Quantities

- *Objective*: describe actual values.
- *Problem*: single measurement leads to approximate value.
- *Solution*: consider a sequence of more and more accurate measuring instruments.
- *Relation*: let X describes results of first k measurements and X' results of $l > k$ measurements.
- The forgetful functor $\pi_{lk} : X' \rightarrow X$ is a *projection*:
 - if $a' \sim' b'$, then $\pi(a') \sim \pi(b')$;
 - if $a \sim b$, then $\exists a', b'$ s.t. $\pi(a') = a$, $\pi(b') = b$, and $a' \sim' b'$.
- *Definition*: $X_1 \xleftarrow{\pi_{2,1}} X_2 \xleftarrow{\pi_{3,2}} X_3 \xleftarrow{\pi_{4,3}} \dots$
- *Actual values*: $x = (x_1, x_2, \dots)$ s.t. $\pi_{21}(x_2) = x_1, \dots$

9. Actual Values: Properties and Examples

- *Equivalence*: $a \sim b$ iff $a_i \sim_i b_i$ for all i .
- *Neighborhoods*: $N_n(a) = \{b \mid b \sim_n a\}$.
- *Limit*: $a^{(k)} \rightarrow a$ iff $\forall n \exists m \forall k > m (a_n^{(k)} \sim_n a)$.
- *Real numbers*: naturally come from intervals.
- *Actually*: we also get $-\infty$ and $+\infty$.
- R^n : naturally comes from n -dimensional boxes.
- “yes”- “no” questions:
 - X_1 : $0 \sim U \sim 1$;
 - X_2 : $0 \sim U0 \sim UU \sim U1 \sim 1, 0 \sim UU \sim 1$;
 - ...
 - projective limit: $0 \sim U \sim 1$.

10. Unusual Property: Compactness

- *General property*: every sequence has a convergent subsequence.
- *Example*: instead of R , we have a compactification $R \cup \{-\infty, +\infty\}$.
- *Potential application*: inverse problems.
- *Description*: we observe $f(x)$ for some continuous $f : X \rightarrow Y$; we want to reconstruct x .
- *Example*: signal from its distortion.
- *Problem*: even if f is 1-1, f^{-1} is discontinuous, so close y lead to different x .
- *Solution*: for compact X , f^{-1} is continuous.
- *Similar property*: \sim is transitive iff

$$\forall n \exists m ((a \sim_m b \& b \sim_m c) \rightarrow (a \sim_n b)).$$

11. Functions

- *Meaning:* $f : A \rightarrow B$ means that:
 - once we know an approximation a_n to a ,
 - we can find some approximation b_m to b .
- *Definition:* a function $f : A \rightarrow B$ is a mapping from $\cup A_n$ to $\cup B_n$ s.t.:
 - $a \sim a'$ implies $f(a) \sim f(a')$;
 - if $a = \pi(a')$, then $f(a) = \pi(f(a'))$.
- *Comment:* functions may be partial, so the results do not converge.
- *Everywhere defined:* if $f : X \rightarrow R$ is everywhere defined, then f is continuous:

$$\forall n \exists m ((x_m \sim_m x'_m) \rightarrow f(x_m) \sim_n f(x'_m)).$$

12. Summary

- *Idea*: restrict ourselves to directly observable results.
- *Measuring instrument*: a finite graph in which:
 - vertices are possible measurement results and
 - vertices a and b are connected by an edge iff a and b can come from measuring the same quantity.
- *Physical quantity*: a sequence of more and more accurate measuring instruments.
- *Resulting mathematical representation*: a projective limits of the corresponding graphs (or complexes).
- *Computational advantage*:
 - *mathematical fact*: higher order objects (functions, operators, etc.) described by similar graphs;
 - *computational advantage*: such higher order objects are algorithmically computable.
