1. General Problem of Data Processing under Uncertainty

- *Indirect measurements*: way to measure y that are difficult (or even impossible) to measure directly.
- *Idea*: $y = f(x_1, \dots, x_n)$

- *Problem*: measurements are never 100% accurate: $\tilde{x}_i \neq x_i$ ($\Delta x_i \neq 0$) hence

$$\tilde{y} = f(\tilde{x}_1, \dots, \tilde{x}_n) \neq y = f(x_1, \dots, x_n).$$

What are bounds on $\Delta y \stackrel{\text{def}}{=} \tilde{y} - y$?

2. Probabilistic and Interval Uncertainty

- *Traditional approach:* we know probability distribution for Δx_i (usually Gaussian).
- *Where it comes from:* calibration using standard MI.
- *Problem:* calibration is not possible in:
 - fundamental science
 - manufacturing
- *Solution:* we know upper bounds Δ_i on $|\Delta x_i|$ hence

$$x_i \in [\tilde{x}_i - \Delta_i, \tilde{x}_i + \Delta_i].$$

3. Interval Computations: A Problem

- *Given:* an algorithm $y = f(x_1, \dots, x_n)$ and n intervals $\mathbf{x}_i = [\underline{x}_i, \bar{x}_i]$.
- *Compute:* the corresponding range of y :
$$[\underline{y}, \bar{y}] = \{f(x_1, \dots, x_n) \mid x_1 \in [\underline{x}_1, \bar{x}_1], \dots, x_n \in [\underline{x}_n, \bar{x}_n]\}.$$
- *Fact:* NP-hard even for quadratic f .
- *Challenge:* when are feasible algorithms possible?
- *Challenge:* when computing $\mathbf{y} = [\underline{y}, \bar{y}]$ is not feasible, find a good approximation $\mathbf{Y} \supseteq \mathbf{y}$.

4. Example 1: Formulation of the Problem

- *Given:*

- $y = f(x_1, x_2) = x_1^2 + x_2^2,$

- $\tilde{x}_1 = 1, \tilde{x}_2 = -1,$

- $\Delta_1 = \Delta_2 = 0.1.$

- In this case, x_1 can be anywhere in

$$[\tilde{x}_1 - \Delta_1, \tilde{x}_1 + \Delta_1] = [1 - 0.1, 1 + 0.1] = [0.9, 1.1].$$

- Similarly, x_2 can be anywhere in

$$[\tilde{x}_2 - \Delta_2, \tilde{x}_2 + \Delta_2] = [-1 - 0.1, -1 + 0.1] = [-1.1, -0.9].$$

- Here, $\tilde{y} = (\tilde{x}_1)^2 + (\tilde{x}_2)^2 = 1^2 + (-1)^2 = 2.$

- *Find:* the range $[\underline{y}, \bar{y}]$ of possible values of y .

5. Example 1: Actual Range

- *Reminder:* $y = x_1^2 + x_2^2 = x_1^2 + |x_2|^2$,

$$x_1 \in [0.9, 1.1], \quad x_2 \in [-1.1, -0.9].$$

- *Actual range:* the function $y = x_1^2 + x_2^2$ is increasing in x_1 and $|x_2|$.
- So, the smallest value of y is

$$\underline{y} = 0.9^2 + (-0.9)^2 = 0.81 + 0.81 = 1.62.$$

- The largest value of y is

$$\bar{y} = 1.1^2 + (-1.1)^2 = 1.21 + 1.21 = 2.42.$$

- Thus, the desired range is $[\underline{y}, \bar{y}] = [1.62, 2.42]$.

6. Exercise 1: Formulation of the Problem

- *Given:*
 - $y = f(x_1, x_2) = x_1^2 - x_1 \cdot x_2 + x_2^2$,
 - $\tilde{x}_1 = 2, \tilde{x}_2 = -2$,
 - $\Delta_1 = \Delta_2 = 0.2$.

- In this case, x_1 can be anywhere in

$$[\tilde{x}_1 - \Delta_1, \tilde{x}_1 + \Delta_1] = [2 - 0.2, 2 + 0.2] = [1.8, 2.2].$$

- Similarly, x_2 can be anywhere in

$$[\tilde{x}_2 - \Delta_2, \tilde{x}_2 + \Delta_2] = [-2 - 0.2, -2 + 0.2] = [-2.2, -1.8].$$

- $\tilde{y} = (\tilde{x}_1)^2 - \tilde{x}_1 \cdot \tilde{x}_2 + (\tilde{x}_2)^2 = 2^2 - 2 \cdot (-2) + (-2)^2 = 12$.
- *Find:* the range $[\underline{y}, \bar{y}]$ of possible values of y .

7. Alternative Approach: Maximum Entropy

- *Situation:* in many practical applications, it is very difficult to come up with the probabilities.
- *Traditional engineering approach:* use probabilistic techniques.
- *Problem:* many different probability distributions are consistent with the same observations.
- *Solution:* select one of these distributions – e.g., the one with the largest entropy.
- *Example – single variable:* if all we know is that $x \in [\underline{x}, \bar{x}]$, then MaxEnt leads to a uniform distribution.
- *Example – multiple variables:* different variables are independently distributed.

8. Limitations of Maximum Entropy Approach

- *Example:* simplest algorithm $y = x_1 + \dots + x_n$.
- *Measurement errors:* $\Delta x_i \in [-\Delta, \Delta]$.
- *Analysis:* $\Delta y = \Delta x_1 + \dots + \Delta x_n$.
- *Worst case situation:* $\Delta y = n \cdot \Delta$.
- *Maximum Entropy approach:* due to Central Limit Theorem, Δy is \approx normal, with $\sigma = \Delta \cdot \frac{\sqrt{n}}{\sqrt{3}}$.
- *Why this may be inadequate:* we get $\Delta \sim \sqrt{n}$, but due to correlation, it is possible that $\Delta = n \cdot \Delta \sim n \gg \sqrt{n}$.
- *Conclusion:* using a single distribution can be very misleading, especially if we want guaranteed results.
- *Examples:* high-risk application areas such as space exploration or nuclear engineering.

9. Linearization is Usually Possible

- In many practical situations, the errors Δx_i are small, so we can ignore quadratic terms:

$$\begin{aligned}\Delta y = \tilde{y} - y &= f(\tilde{x}_1, \dots, \tilde{x}_n) - f(x_1, \dots, x_n) = \\ &= f(\tilde{x}_1, \dots, \tilde{x}_n) - f(\tilde{x}_1 - \Delta x_1, \dots, \tilde{x}_n - \Delta x_n) \approx \\ &= c_1 \cdot \Delta x_1 + \dots + c_n \cdot \Delta x_n,\end{aligned}$$

where $c_i \stackrel{\text{def}}{=} \frac{\partial f}{\partial x_i}(\tilde{x}_1, \dots, \tilde{x}_n)$.

- For a linear function, the largest Δy is obtained when each term $c_i \cdot \Delta x_i$ is the largest:

$$\Delta = |c_1| \cdot \Delta_1 + \dots + |c_n| \cdot \Delta_n.$$

- Due to the linearization assumption, we can estimate each partial derivative c_i as

$$c_i \approx \frac{f(\tilde{x}_1, \dots, \tilde{x}_{i-1}, \tilde{x}_i + h_i, \tilde{x}_{i+1}, \dots, \tilde{x}_n) - \tilde{y}}{h_i}.$$

10. Example 1: Reminder

- *Given:*

- $y = f(x_1, x_2) = x_1^2 + x_2^2,$

- $\tilde{x}_1 = 1, \tilde{x}_2 = -1,$

- $\Delta_1 = \Delta_2 = 0.1.$

- In this case, x_1 can be anywhere in

$$[\tilde{x}_1 - \Delta_1, \tilde{x}_1 + \Delta_1] = [1 - 0.1, 1 + 0.1] = [0.9, 1.1].$$

- Similarly, x_2 can be anywhere in

$$[\tilde{x}_2 - \Delta_2, \tilde{x}_2 + \Delta_2] = [-1 - 0.1, -1 + 0.1] = [-1.1, -0.9].$$

- Here, $\tilde{y} = (\tilde{x}_1)^2 + (\tilde{x}_2)^2 = 1^2 + (-1)^2 = 2.$

- *Find:* the range $[\underline{y}, \bar{y}]$ of possible values of y .

11. Example 1: Solution by Linearization

- *Reminder:* $y = x_1^2 + x_2^2$, $\tilde{y} = 2$.
- Here:

$$c_1 = \frac{\partial f}{\partial x_i}(\tilde{x}_1, \dots, \tilde{x}_n) = 2\tilde{x}_1 = 2 \cdot 1 = 2;$$

$$c_2 = \frac{\partial f}{\partial x_i}(\tilde{x}_1, \dots, \tilde{x}_n) = 2\tilde{x}_2 = 2 \cdot (-1) = -2.$$

- Thus,

$$\begin{aligned}\Delta &= |c_1| \cdot \Delta_1 + |c_2| \cdot \Delta_2 = 2 \cdot 0.1 + |-2| \cdot 0.1 = \\ &2 \cdot 0.1 + 2 \cdot 0.1 = 0.4.\end{aligned}$$

- *Estimated range:*

$$[\tilde{y} - \Delta, \tilde{y} + \Delta] = [2 - 0.4, 2 + 0.4] = [1.6, 2.4].$$

- *Comment.* This is close to the actual range $[1.62, 2.42]$.

12. Exercise 2

- Given:

- $y = f(x_1, x_2) = x_1^2 - x_1 \cdot x_2 + x_2^2,$

- $\tilde{x}_1 = 2, \tilde{x}_2 = -2,$

- $\Delta_1 = \Delta_2 = 0.2.$

- In this case, x_1 can be anywhere in

$$[\tilde{x}_1 - \Delta_1, \tilde{x}_1 + \Delta_1] = [2 - 0.2, 2 + 0.2] = [1.8, 2.2].$$

- Similarly, x_2 can be anywhere in

$$[\tilde{x}_2 - \Delta_2, \tilde{x}_2 + \Delta_2] = [-2 - 0.2, -2 + 0.2] = [-2.2, -1.8].$$

- $\tilde{y} = (\tilde{x}_1)^2 - \tilde{x}_1 \cdot \tilde{x}_2 + (\tilde{x}_2)^2 = 2^2 - 2 \cdot (-2) + (-2)^2 = 12.$

- Task: use linearization to find the range $[\underline{y}, \bar{y}]$ of possible values of y .

[General Problem of...](#)[Cauchy Deviates Method](#)[Interval Arithmetic...](#)[Case Study: Chip Design](#)[Combining Interval...](#)[Case Study...](#)[Case Study: Detecting...](#)[Home Page](#)[Title Page](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 13 of 80](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

13. Linearization: Algorithm

To compute the range \mathbf{y} of y , we do the following.

- First, we apply the algorithm f to the original estimates $\tilde{x}_1, \dots, \tilde{x}_n$, resulting in the value $\tilde{y} = f(\tilde{x}_1, \dots, \tilde{x}_n)$.
- Second, for all i from 1 to n ,
 - we compute $f(\tilde{x}_1, \dots, \tilde{x}_{i-1}, \tilde{x}_i + h_i, \tilde{x}_{i+1}, \dots, \tilde{x}_n)$ for some small h_i and then
 - we compute

$$c_i = \frac{f(\tilde{x}_1, \dots, \tilde{x}_{i-1}, \tilde{x}_i + h_i, \tilde{x}_{i+1}, \dots, \tilde{x}_n) - \tilde{y}}{h_i}.$$

- Finally, we compute $\Delta = |c_1| \cdot \Delta_1 + \dots + |c_n| \cdot \Delta_n$ and the desired range $\mathbf{y} = [\tilde{y} - \Delta, \tilde{y} + \Delta]$.
- *Problem:* we need $n + 1$ calls to f , and this is often too long.

15. Example 1: Solution 2 by Linearization

- *Reminder:* $f(x_1, x_2) = x_1^2 + x_2^2$, $\tilde{y} = 2$.

- Let us take $h_1 = h_2 = 0.1$; then:

$$c_1 = \frac{f(\tilde{x}_1 + 0.1, \tilde{x}_2) - \tilde{y}}{0.1} = \frac{(\tilde{x}_1 + 0.1)^2 + (\tilde{x}_2)^2 - 2}{0.1} =$$

$$\frac{1.1^2 + 1 - 2}{0.1} = \frac{1.21 + 1 - 2}{0.1} = \frac{0.21}{0.1} = 2.1;$$

$$c_2 = \frac{f(\tilde{x}_1, \tilde{x}_2 + 0.1) - \tilde{y}}{0.1} = \frac{(\tilde{x}_1)^2 + (\tilde{x}_2 + 0.1)^2 - 2}{0.1} =$$

$$\frac{1^2 + (-0.9)^2 - 2}{0.1} = \frac{1 + 0.81 - 2}{0.1} = \frac{-0.19}{0.1} = -1.9.$$

$$\Delta = |c_1| \cdot \Delta_1 + |c_2| \cdot \Delta_2 = 2.1 \cdot 0.1 + |-1.9| \cdot 0.1 = 2.1 \cdot 0.1 + 1.9 \cdot 0.1 = 0.4.$$

- *Estimated range:*

$$[\tilde{y} - \Delta, \tilde{y} + \Delta] = [2 - 0.4, 2 + 0.4] = [1.6, 2.4].$$

- *Comment.* This is close to the actual range $[1.62, 2.42]$.

17. Cauchy Deviate Method: Idea

- For large n , we can further reduce the number of calls to f if we Cauchy distributions, w/pdf

$$\rho(z) = \frac{\Delta}{\pi \cdot (z^2 + \Delta^2)}.$$

- Known property of Cauchy transforms:
 - if z_1, \dots, z_n are independent Cauchy random variables w/parameters $\Delta_1, \dots, \Delta_n$,
 - then $z = c_1 \cdot z_1 + \dots + c_n \cdot z_n$ is also Cauchy distributed, w/parameter

$$\Delta = |c_1| \cdot \Delta_1 + \dots + |c_n| \cdot \Delta_n.$$

- This is exactly what we need to estimate interval uncertainty!

18. Cauchy Deviate Method: Towards Implementation

- To implement the Cauchy idea, we must answer the following questions:
 - how to simulate the Cauchy distribution; and
 - how to estimate the parameter Δ of this distribution from a finite sample.
- Simulation can be based on the functional transformation of uniformly distributed sample values:

$$\delta_i = \Delta_i \cdot \tan(\pi \cdot (r_i - 0.5)), \text{ where } r_i \sim U([0, 1]).$$

- To estimate Δ , we can apply the Maximum Likelihood Method $\rho(\delta^{(1)}) \cdot \rho(\delta^{(2)}) \cdot \dots \cdot \rho(\delta^{(N)}) \rightarrow \max$, i.e., solve

$$\frac{1}{1 + \left(\frac{\delta^{(1)}}{\Delta}\right)^2} + \dots + \frac{1}{1 + \left(\frac{\delta^{(N)}}{\Delta}\right)^2} = \frac{N}{2}.$$

19. Cauchy Deviates Method: Algorithm

- Apply f to \tilde{x}_i ; we get $\tilde{y} := f(\tilde{x}_1, \dots, \tilde{x}_n)$.
- For $k = 1, 2, \dots, N$, repeat the following:
 - use the standard RNG to draw $r_i^{(k)} \sim U([0, 1])$,
 $i = 1, 2, \dots, n$;
 - compute Cauchy distributed values
 $c_i^{(k)} := \tan(\pi \cdot (r_i^{(k)} - 0.5))$;
 - compute $K := \max_i |c_i^{(k)}|$ and normalized errors
 $\delta_i^{(k)} := \Delta_i \cdot c_i^{(k)} / K$;
 - compute the simulated “actual values”
 $x_i^{(k)} := \tilde{x}_i - \delta_i^{(k)}$;
 - compute simulated errors of indirect measurement:
 $\delta^{(k)} := K \cdot \left(\tilde{y} - f \left(x_1^{(k)}, \dots, x_n^{(k)} \right) \right)$;
- Compute Δ by applying the bisection method to solve the Maximum Likelihood equation.

20. Important Comment

- To avoid confusion, we should emphasize that:
 - in contrast to the Monte-Carlo solution for the probabilistic case,
 - the use of Cauchy distribution in the interval case is a computational trick,
 - it is *not* a truthful simulation of the actual measurement error Δx_i .
- Indeed:
 - we know that the actual value of Δx_i is always inside the interval $[-\Delta_i, \Delta_i]$, but
 - a Cauchy distributed random attains values outside this interval as well.

21. Approximate Methods – Such As Linearizaion – Are Sometimes Not Sufficient

- In many application areas, it is sufficient to have an *approximate* estimate of y .
- Sometimes, we need to *guarantee* that y does not exceed a certain threshold y_0 . Examples:
 - in *nuclear engineering*, the temperatures and the neutron flows should not exceed the critical values;
 - a space ship lands on the planet and does not fly past it, etc.
- The only way to guarantee this is to have an interval $\mathbf{Y} = [\underline{Y}, \overline{Y}]$ for which $\mathbf{y} \subseteq \mathbf{Y}$ and $\overline{Y} \leq y_0$.
- Such an interval is called an *enclosure*.
- Computing such an enclosure is one of the main tasks of interval computations.

22. Interval Computations: A Brief History

- *Origins*: Archimedes (Ancient Greece)
- *Modern pioneers*: Warmus (Poland), Sunaga (Japan), Moore (USA), 1956–59
- *First boom*: early 1960s.
- *First challenge*: taking interval uncertainty into account when planning spaceflights to the Moon.
- *Current applications* (sample):
 - design of elementary particle colliders: Berz, Kyoko (USA)
 - will a comet hit the Earth: Berz, Moore (USA)
 - robotics: Jaulin (France), Neumaier (Austria)
 - chemical engineering: Stadtherr (USA)

23. Interval Arithmetic: Foundations of Interval Techniques

- *Problem:* compute the range

$$[\underline{y}, \bar{y}] = \{f(x_1, \dots, x_n) \mid x_1 \in [\underline{x}_1, \bar{x}_1], \dots, x_n \in [\underline{x}_n, \bar{x}_n]\}.$$

- *Interval arithmetic:* for arithmetic operations $f(x_1, x_2)$ (and for elementary functions), we have explicit formulas for the range.

- *Examples:* when $x_1 \in \mathbf{x}_1 = [\underline{x}_1, \bar{x}_1]$ and $x_2 \in \mathbf{x}_2 = [\underline{x}_2, \bar{x}_2]$, then:

- The range $\mathbf{x}_1 + \mathbf{x}_2$ for $x_1 + x_2$ is $[\underline{x}_1 + \underline{x}_2, \bar{x}_1 + \bar{x}_2]$.
- The range $\mathbf{x}_1 - \mathbf{x}_2$ for $x_1 - x_2$ is $[\underline{x}_1 - \bar{x}_2, \bar{x}_1 - \underline{x}_2]$.
- The range $\mathbf{x}_1 \cdot \mathbf{x}_2$ for $x_1 \cdot x_2$ is $[\underline{y}, \bar{y}]$, where

$$\underline{y} = \min(\underline{x}_1 \cdot \underline{x}_2, \underline{x}_1 \cdot \bar{x}_2, \bar{x}_1 \cdot \underline{x}_2, \bar{x}_1 \cdot \bar{x}_2);$$

$$\bar{y} = \max(\underline{x}_1 \cdot \underline{x}_2, \underline{x}_1 \cdot \bar{x}_2, \bar{x}_1 \cdot \underline{x}_2, \bar{x}_1 \cdot \bar{x}_2).$$

- The range $1/\mathbf{x}_1$ for $1/x_1$ is $[1/\bar{x}_1, 1/\underline{x}_1]$ (if $0 \notin \mathbf{x}_1$).

24. Example

Let $\mathbf{x}_1 = [1, 2]$ and $\mathbf{x}_2 = [-3, 1]$. Then:

$$\mathbf{x}_1 + \mathbf{x}_2 = [1, 2] + [-3, 1] = [1 + (-3), 2 + 1] = [-2, 3];$$

$$\mathbf{x}_1 - \mathbf{x}_2 = [1, 2] - [-3, 1] = [1 - (-3), 2 - 1] = [4, 1];$$

$$\mathbf{x}_1 \cdot \mathbf{x}_2 = [1, 2] \cdot [-3, 1] =$$

$$[\min(1 \cdot (-3), 1 \cdot 1, 2 \cdot (-3), 2 \cdot 1), \max(1 \cdot (-3), 1 \cdot 1, 2 \cdot (-3), 2 \cdot 1)] =$$

$$[\min(-3, 1, -6, 2), \max(-3, 1, -6, 2)] = [-6, 2];$$

$$1/\mathbf{x}_1 = 1/[1, 2] = [1/2, 1/1] = [0.5, 1].$$

26. Straightforward Interval Computations: Example

- *Example:* $f(x) = (x - 2) \cdot (x + 2)$, $x \in [1, 2]$.
- How will the computer compute it?
 - $r_1 := x - 2$;
 - $r_2 := x + 2$;
 - $r_3 := r_1 \cdot r_2$.
- *Main idea:* perform the same operations, but with *intervals* instead of *numbers*:
 - $\mathbf{r}_1 := [1, 2] - [2, 2] = [-1, 0]$;
 - $\mathbf{r}_2 := [1, 2] + [2, 2] = [3, 4]$;
 - $\mathbf{r}_3 := [-1, 0] \cdot [3, 4] = [-4, 0]$.
- *Actual range:* $f(\mathbf{x}) = [-3, 0]$.
- *Comment:* this is just a toy example, there are more efficient ways of computing an enclosure $\mathbf{Y} \supseteq \mathbf{y}$.

27. Exercise 5: Task

Use straightforward interval computations to compute the range of the function $f(x) = (x - 1) \cdot (x + 1)$ for $x \in [0, 2]$.

[General Problem of ...](#)[Cauchy Deviates Method](#)[Interval Arithmetic: ...](#)[Case Study: Chip Design](#)[Combining Interval ...](#)[Case Study: ...](#)[Case Study: Detecting ...](#)[Home Page](#)[Title Page](#)[◀◀](#)[▶▶](#)[◀](#)[▶](#)[Page 28 of 80](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

28. First Idea: Use of Monotonicity

- *Reminder:* for arithmetic, we had exact ranges.
- *Reason:* $+$, $-$, \cdot are monotonic in each variable.
- *How monotonicity helps:* if $f(x_1, \dots, x_n)$ is (non-strictly) increasing ($f \uparrow$) in each x_i , then

$$f(\mathbf{x}_1, \dots, \mathbf{x}_n) = [f(\underline{x}_1, \dots, \underline{x}_n), f(\bar{x}_1, \dots, \bar{x}_n)].$$

- *Similarly:* if $f \uparrow$ for some x_i and $f \downarrow$ for other x_j .
- *Fact:* $f \uparrow$ in x_i if $\frac{\partial f}{\partial x_i} \geq 0$.
- *Checking monotonicity:* check that the range $[\underline{r}_i, \bar{r}_i]$ of $\frac{\partial f}{\partial x_i}$ on \mathbf{x}_i has $\underline{r}_i \geq 0$.
- *Differentiation:* by Automatic Differentiation (AD) tools.
- *Estimating ranges of $\frac{\partial f}{\partial x_i}$:* straightforward interval comp.

29. Monotonicity: Example

- *Idea:* if the range $[\underline{r}_i, \bar{r}_i]$ of each $\frac{\partial f}{\partial x_i}$ on \mathbf{x}_i has $\underline{r}_i \geq 0$, then

$$f(\mathbf{x}_1, \dots, \mathbf{x}_n) = [f(\underline{x}_1, \dots, \underline{x}_n), f(\bar{x}_1, \dots, \bar{x}_n)].$$

- *Example:* $f(x) = (x - 2) \cdot (x + 2)$, $\mathbf{x} = [1, 2]$.
- *Case $n = 1$:* if the range $[\underline{r}, \bar{r}]$ of $\frac{df}{dx}$ on \mathbf{x} has $\underline{r} \geq 0$, then

$$f(\mathbf{x}) = [f(\underline{x}), f(\bar{x})].$$

- *AD:* $\frac{df}{dx} = 1 \cdot (x + 2) + (x - 2) \cdot 1 = 2x$.
- *Checking:* $[\underline{r}, \bar{r}] = [2, 4]$, with $2 \geq 0$.
- *Result:* $f([1, 2]) = [f(1), f(2)] = [-3, 0]$.
- *Comparison:* this is the exact range.

[General Problem of ...](#)[Cauchy Deviates Method](#)[Interval Arithmetic: ...](#)[Case Study: Chip Design](#)[Combining Interval ...](#)[Case Study: ...](#)[Case Study: Detecting ...](#)[Home Page](#)[Title Page](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 30 of 80](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

30. Exercise 6: Task

31. Non-Monotonic Example

- *Example:* $f(x) = x \cdot (1 - x)$, $x \in [0, 1]$.
- How will the computer compute it?
 - $r_1 := 1 - x$;
 - $r_2 := x \cdot r_1$.
- *Straightforward interval computations:*
 - $\mathbf{r}_1 := [1, 1] - [0, 1] = [0, 1]$;
 - $\mathbf{r}_2 := [0, 1] \cdot [0, 1] = [0, 1]$.
- *Actual range:* min, max of f at \underline{x} , \bar{x} , or when $\frac{df}{dx} = 0$.
- Here, $\frac{df}{dx} = 1 - 2x = 0$ for $x = 0.5$, thus we:
 - compute $f(0) = 0$, $f(0.5) = 0.25$, and $f(1) = 0$, so
 - $\underline{y} = \min(0, 0.25, 0) = 0$, $\bar{y} = \max(0, 0.25, 0) = 0.25$.
- *Resulting range:* $f(\mathbf{x}) = [0, 0.25]$.

32. Second Idea: Centered Form

- *Main idea:* Intermediate Value Theorem

$$f(x_1, \dots, x_n) = f(\tilde{x}_1, \dots, \tilde{x}_n) + \sum_{i=1}^n \frac{\partial f}{\partial x_i}(\chi) \cdot (x_i - \tilde{x}_i)$$

for some $\chi_i \in \mathbf{x}_i$.

- *Corollary:* $f(x_1, \dots, x_n) \in \mathbf{Y}$, where

$$\mathbf{Y} = \tilde{y} + \sum_{i=1}^n \frac{\partial f}{\partial x_i}(\mathbf{x}_1, \dots, \mathbf{x}_n) \cdot [-\Delta_i, \Delta_i].$$

- *Differentiation:* by Automatic Differentiation (AD) tools.
- *Estimating the ranges of derivatives:*
 - if appropriate, by monotonicity, or
 - by straightforward interval computations, or
 - by centered form (more time but more accurate).

33. Centered Form: Example

- *General formula:*

$$\mathbf{Y} = f(\tilde{x}_1, \dots, \tilde{x}_n) + \sum_{i=1}^n \frac{\partial f}{\partial x_i}(\mathbf{x}_1, \dots, \mathbf{x}_n) \cdot [-\Delta_i, \Delta_i].$$

- *Example:* $f(x) = x \cdot (1 - x)$, $\mathbf{x} = [0, 1]$.
- Here, $\mathbf{x} = [\tilde{x} - \Delta, \tilde{x} + \Delta]$, with $\tilde{x} = 0.5$ and $\Delta = 0.5$.
- *Case $n = 1$:* $\mathbf{Y} = f(\tilde{x}) + \frac{df}{dx}(\mathbf{x}) \cdot [-\Delta, \Delta]$.
- *AD:* $\frac{df}{dx} = 1 \cdot (1 - x) + x \cdot (-1) = 1 - 2x$.
- *Estimation:* we have $\frac{df}{dx}(\mathbf{x}) = 1 - 2 \cdot [0, 1] = [-1, 1]$.
- *Result:* $\mathbf{Y} = 0.5 \cdot (1 - 0.5) + [-1, 1] \cdot [-0.5, 0.5] = 0.25 + [-0.5, 0.5] = [-0.25, 0.75]$.
- *Comparison:* actual range $[0, 0.25]$, straightforward $[0, 1]$.

35. Third Idea: Bisection

- *Known:* accuracy $O(\Delta_i^2)$ of first order formula

$$f(x_1, \dots, x_n) = f(\tilde{x}_1, \dots, \tilde{x}_n) + \sum_{i=1}^n \frac{\partial f}{\partial x_i}(\chi) \cdot (x_i - \tilde{x}_i).$$

- *Idea:* if the intervals are too wide, we:
 - split one of them in half ($\Delta_i^2 \rightarrow \Delta_i^2/4$); and
 - take the union of the resulting ranges.
- *Example:* $f(x) = x \cdot (1 - x)$, where $x \in \mathbf{x} = [0, 1]$.
- *Split:* take $\mathbf{x}' = [0, 0.5]$ and $\mathbf{x}'' = [0.5, 1]$.
- *1st range:* $1 - 2 \cdot \mathbf{x} = 1 - 2 \cdot [0, 0.5] = [0, 1]$, so $f \uparrow$ and $f(\mathbf{x}') = [f(0), f(0.5)] = [0, 0.25]$.
- *2nd range:* $1 - 2 \cdot \mathbf{x} = 1 - 2 \cdot [0.5, 1] = [-1, 0]$, so $f \downarrow$ and $f(\mathbf{x}'') = [f(1), f(0.5)] = [0, 0.25]$.
- *Result:* $f(\mathbf{x}') \cup f(\mathbf{x}'') = [0, 0.25]$ – exact.

37. Alternative Approach: Affine Arithmetic

- *So far:* we compute the range of $x \cdot (1 - x)$ by multiplying ranges of x and $1 - x$.
- *We ignore:* that both factors depend on x and are, thus, dependent.
- *Idea:* for each intermediate result a , keep an explicit dependence on $\Delta x_i = \tilde{x}_i - x_i$ (at least its linear terms).
- *Implementation:*

$$a = a_0 + \sum_{i=1}^n a_i \cdot \Delta x_i + [\underline{a}, \bar{a}].$$

- *We start:* with $x_i = \tilde{x}_i - \Delta x_i$, i.e.,
 $\tilde{x}_i + 0 \cdot \Delta x_1 + \dots + 0 \cdot \Delta x_{i-1} + (-1) \cdot \Delta x_i + 0 \cdot \Delta x_{i+1} + \dots + 0 \cdot \Delta x_n + [0, 0]$.
- *Description:* $a_0 = \tilde{x}_i$, $a_i = -1$, $a_j = 0$ for $j \neq i$, and $[\underline{a}, \bar{a}] = [0, 0]$.

38. Affine Arithmetic: Operations

- *Representation:* $a = a_0 + \sum_{i=1}^n a_i \cdot \Delta x_i + [\underline{a}, \bar{a}]$.
- *Input:* $a = a_0 + \sum_{i=1}^n a_i \cdot \Delta x_i + \mathbf{a}$ and $b = b_0 + \sum_{i=1}^n b_i \cdot \Delta x_i + \mathbf{b}$.
- *Operations:* $c = a \otimes b$.
- *Addition:* $c_0 = a_0 + b_0$, $c_i = a_i + b_i$, $\mathbf{c} = \mathbf{a} + \mathbf{b}$.
- *Subtraction:* $c_0 = a_0 - b_0$, $c_i = a_i - b_i$, $\mathbf{c} = \mathbf{a} - \mathbf{b}$.
- *Multiplication:* $c_0 = a_0 \cdot b_0$, $c_i = a_0 \cdot b_i + b_0 \cdot a_i$,
 $\mathbf{c} = a_0 \cdot \mathbf{b} + b_0 \cdot \mathbf{a} + \sum_{i \neq j} a_i \cdot b_j \cdot [-\Delta_i, \Delta_i] \cdot [-\Delta_j, \Delta_j] +$
 $\sum_i a_i \cdot b_i \cdot [-\Delta_i, \Delta_i]^2 +$
 $\left(\sum_i a_i \cdot [-\Delta_i, \Delta_i] \right) \cdot \mathbf{b} + \left(\sum_i b_i \cdot [-\Delta_i, \Delta_i] \right) \cdot \mathbf{a} + \mathbf{a} \cdot \mathbf{b}.$

39. Affine Arithmetic: Example

- *Example:* $f(x) = x \cdot (1 - x)$, $x \in [0, 1]$.
- Here, $n = 1$, $\tilde{x} = 0.5$, and $\Delta = 0.5$.
- How will the computer compute it?
 - $r_1 := 1 - x$;
 - $r_2 := x \cdot r_1$.
- *Affine arithmetic:* we start with $x = 0.5 - \Delta x + [0, 0]$;
 - $\mathbf{r}_1 := 1 - (0.5 - \Delta x) = 0.5 + \Delta x$;
 - $\mathbf{r}_2 := (0.5 - \Delta x) \cdot (0.5 + \Delta x)$, i.e.,
$$\mathbf{r}_2 = 0.25 + 0 \cdot \Delta x - [-\Delta, \Delta]^2 = 0.25 + [-\Delta^2, 0].$$
- *Resulting range:* $\mathbf{y} = 0.25 + [-0.25, 0] = [0, 0.25]$.
- *Comparison:* this is the exact range.

41. Affine Arithmetic: Towards More Accurate Estimates

- *In our simple example:* we got the exact range.
- *In general:* range estimation is NP-hard.
- *Meaning:* a feasible (polynomial-time) algorithm will sometimes lead to excess width: $\mathbf{Y} \supset \mathbf{y}$.
- *Conclusion:* affine arithmetic may lead to excess width.
- *Question:* how to get more accurate estimates?
- *First idea:* bisection.
- *Second idea* (Taylor arithmetic):
 - *affine arithmetic:* $a = a_0 + \sum a_i \cdot \Delta x_i + \mathbf{a}$;
 - *meaning:* we keep linear terms in Δx_i ;
 - *idea:* keep, e.g., quadratic terms

$$a = a_0 + \sum a_i \cdot \Delta x_i + \sum a_{ij} \cdot \Delta x_i \cdot \Delta x_j + \mathbf{a}.$$

42. Interval Computations vs. Affine Arithmetic: Comparative Analysis

- *Objective:* we want a method that computes a reasonable estimate for the range in reasonable time.
- *Conclusion – how to compare different methods:*
 - how accurate are the estimates, and
 - how fast we can compute them.
- *Accuracy:* affine arithmetic leads to more accurate ranges.
- *Computation time:*
 - *Interval arithmetic:* for each intermediate result a , we compute two values: endpoints \underline{a} and \bar{a} of $[\underline{a}, \bar{a}]$.
 - *Affine arithmetic:* for each a , we compute $n + 3$ values:

$$a_0 \quad a_1, \dots, a_n \quad \underline{a}, \bar{a}.$$

- *Conclusion:* affine arithmetic is $\sim n$ times slower.

43. Solving Systems of Equations: Extending Known Algorithms to Situations with Interval Uncertainty

- *We have:* a system of equations $g_i(y_1, \dots, y_n) = a_i$ with unknowns y_i ;
- *We know:* a_i with interval uncertainty: $a_i \in [\underline{a}_i, \bar{a}_i]$;
- *We want:* to find the corresponding ranges of y_j .
- *First case:* for exactly known a_i , we have an algorithm $y_j = f_j(a_1, \dots, a_n)$ for solving the system.
- *Example:* system of linear equations.
- *Solution:* apply interval computations techniques to find the range $f_j([\underline{a}_1, \bar{a}_1], \dots, [\underline{a}_n, \bar{a}_n])$.
- *Better solution:* for specific equations, we often already know which ideas work best.
- *Example:* linear equations $Ay = b$; y is monotonic in b .

44. Solving Systems of Equations When No Algorithm Is Known

- *Idea:*
 - parse each equation into elementary constraints, and
 - use interval computations to improve original ranges until we get a narrow range (= solution).
- *First example:* $x - x^2 = 0.5$, $x \in [0, 1]$ (no solution).
- *Parsing:* $r_1 = x^2$, $0.5 (= r_2) = x - r_1$.
- *Rules:* from $r_1 = x^2$, we extract two rules:

$$(1) x \rightarrow r_1 = x^2; \quad (2) r_1 \rightarrow x = \sqrt{r_1};$$

from $0.5 = x - r_1$, we extract two more rules:

$$(3) x \rightarrow r_1 = x - 0.5; \quad (4) r_1 \rightarrow x = r_1 + 0.5.$$

45. Solving Systems of Equations When No Algorithm Is Known: Example

- (1) $r = x^2$; (2) $x = \sqrt{r}$; (3) $r = x - 0.5$; (4) $x = r + 0.5$.

- We start with: $\mathbf{x} = [0, 1]$, $\mathbf{r} = (-\infty, \infty)$.

(1) $\mathbf{r} = [0, 1]^2 = [0, 1]$, so $\mathbf{r}_{\text{new}} = (-\infty, \infty) \cap [0, 1] = [0, 1]$.

(2) $\mathbf{x}_{\text{new}} = \sqrt{[0, 1]} \cap [0, 1] = [0, 1]$ – no change.

(3) $\mathbf{r}_{\text{new}} = ([0, 1] - 0.5) \cap [0, 1] = [-0.5, 0.5] \cap [0, 1] = [0, 0.5]$.

(4) $\mathbf{x}_{\text{new}} = ([0, 0.5] + 0.5) \cap [0, 1] = [0.5, 1] \cap [0, 1] = [0.5, 1]$.

(1) $\mathbf{r}_{\text{new}} = [0.5, 1]^2 \cap [0, 0.5] = [0.25, 0.5]$.

(2) $\mathbf{x}_{\text{new}} = \sqrt{[0.25, 0.5]} \cap [0.5, 1] = [0.5, 0.71]$;
round \underline{a} down \downarrow and \bar{a} up \uparrow , to guarantee enclosure.

(3) $\mathbf{r}_{\text{new}} = ([0.5, 0.71] - 0.5) \cap [0.25, 0.5] = [0, 0.21] \cap [0.25, 0.5]$,
i.e., $\mathbf{r}_{\text{new}} = \emptyset$.

- *Conclusion:* the original equation has no solutions.

46. Solving Systems of Equations: 2nd Example

- *Example:* $x - x^2 = 0$, $x \in [0, 1]$.
- *Parsing:* $r_1 = x^2$, $0 (= r_2) = x - r_1$.
- *Rules:* (1) $r = x^2$; (2) $x = \sqrt{r}$; (3) $r = x$; (4) $x = r$.
- *We start with:* $\mathbf{x} = [0, 1]$, $\mathbf{r} = (-\infty, \infty)$.
- *Problem:* after Rule 1, we're stuck with $\mathbf{x} = \mathbf{r} = [0, 1]$.
- *Solution:* bisect $\mathbf{x} = [0, 1]$ into $[0, 0.5]$ and $[0.5, 1]$.
- *For 1st subinterval:*
 - Rule 1 leads to $\mathbf{r}_{\text{new}} = [0, 0.5]^2 \cap [0, 0.5] = [0, 0.25]$;
 - Rule 4 leads to $\mathbf{x}_{\text{new}} = [0, 0.25]$;
 - Rule 1 leads to $\mathbf{r}_{\text{new}} = [0, 0.25]^2 = [0, 0.0625]$;
 - Rule 4 leads to $\mathbf{x}_{\text{new}} = [0, 0.0625]$; etc.
 - we converge to $x = 0$.
- *For 2nd subinterval:* we converge to $x = 1$.

48. Optimization: Extending Known Algorithms to Situations with Interval Uncertainty

- *Problem:* find y_1, \dots, y_m for which

$$g(y_1, \dots, y_m, a_1, \dots, a_m) \rightarrow \max.$$

- *We know:* a_i with interval uncertainty: $a_i \in [\underline{a}_i, \bar{a}_i]$;
- *We want:* to find the corresponding ranges of y_j .
- *First case:* for exactly known a_i , we have an algorithm $y_j = f_j(a_1, \dots, a_n)$ for solving the optimization problem.
- *Example:* quadratic objective function g .
- *Solution:* apply interval computations techniques to find the range $f_j([\underline{a}_1, \bar{a}_1], \dots, [\underline{a}_n, \bar{a}_n])$.
- *Better solution:* for specific f , we often already know which ideas work best.

49. Optimization When No Algorithm Is Known

- *Idea:* divide the original box \mathbf{x} into subboxes \mathbf{b} .
- If $\max_{x \in \mathbf{b}} g(x) < g(x')$ for a known x' , dismiss \mathbf{b} .
- *Example:* $g(x) = x \cdot (1 - x)$, $\mathbf{x} = [0, 1]$.
- Divide into 10 (?) subboxes $\mathbf{b} = [0, 0.1], [0.1, 0.2], \dots$
- Find $g(\tilde{b})$ for each \mathbf{b} ; the largest is $0.45 \cdot 0.55 = 0.2475$.
- Compute $G(\mathbf{b}) = g(\tilde{b}) + (1 - 2 \cdot \mathbf{b}) \cdot [-\Delta, \Delta]$.
- Dismiss subboxes for which $\bar{Y} < 0.2475$.
- *Example:* for $[0.2, 0.3]$, we have
$$0.25 \cdot (1 - 0.25) + (1 - 2 \cdot [0.2, 0.3]) \cdot [-0.05, 0.05].$$
- Here $\bar{Y} = 0.2175 < 0.2475$, so we dismiss $[0.2, 0.3]$.
- *Result:* keep only boxes $\subseteq [0.3, 0.7]$.
- *Further subdivision:* get us closer and closer to $x = 0.5$.

51. Case Study: Chip Design

- *Chip design*: one of the main objectives is to decrease the clock cycle.
- *Current approach*: uses worst-case (interval) techniques.
- *Problem*: the probability of the worst-case values is usually very small.
- *Result*: estimates are over-conservative – unnecessary over-design and under-performance of circuits.
- *Difficulty*: we only have *partial* information about the corresponding probability distributions.
- *Objective*: produce estimates valid for all distributions which are consistent with this information.
- *What we do*: provide such estimates for the clock time.

52. Estimating Clock Cycle: a Practical Problem

- *Objective:* estimate the clock cycle on the design stage.
- The clock cycle of a chip is constrained by the maximum path delay over all the circuit paths

$$D \stackrel{\text{def}}{=} \max(D_1, \dots, D_N).$$

- The path delay D_i along the i -th path is the sum of the delays corresponding to the gates and wires along this path.
- Each of these delays, in turn, depends on several factors such as:
 - the variation caused by the current design practices,
 - environmental design characteristics (e.g., variations in temperature and in supply voltage), etc.

53. Traditional (Interval) Approach to Estimating the Clock Cycle

- *Traditional approach:* assume that each factor takes the worst possible value.
- *Result:* time delay when all the factors are at their worst.
- *Problem:*
 - different factors are usually independent;
 - combination of worst cases is improbable.
- *Computational result:* current estimates are 30% above the observed clock time.
- *Practical result:* the clock time is set too high – chips are over-designed and under-performing.

54. Robust Statistical Methods Are Needed

- *Ideal case*: we know probability distributions.
- *Solution*: Monte-Carlo simulations.
- *In practice*: we only have *partial* information about the distributions of some of the parameters; usually:
 - the mean, and
 - some characteristic of the deviation from the mean
 - e.g., the interval that is guaranteed to contain possible values of this parameter.
- *Possible approach*: Monte-Carlo with several possible distributions.
- *Problem*: no guarantee that the result is a valid bound for all possible distributions.
- *Objective*: provide *robust* bounds, i.e., bounds that work for all possible distributions.

55. Towards a Mathematical Formulation of the Problem

- *General case:* each gate delay d depends on the difference x_1, \dots, x_n between the actual and the nominal values of the parameters.
- *Main assumption:* these differences are usually small.
- Each path delay D_i is the sum of gate delays.
- *Conclusion:* D_i is a linear function: $D_i = a_i + \sum_{j=1}^n a_{ij} \cdot x_j$
for some a_i and a_{ij} .
- The desired maximum delay $D = \max_i D_i$ has the form

$$D = F(x_1, \dots, x_n) \stackrel{\text{def}}{=} \max_i \left(a_i + \sum_{j=1}^n a_{ij} \cdot x_j \right).$$

56. Towards a Mathematical Formulation of the Problem (cont-d)

- *Known*: maxima of linear function are exactly convex functions:

$$F(\alpha \cdot x + (1 - \alpha) \cdot y) \leq \alpha \cdot F(x) + (1 - \alpha) \cdot F(y)$$

for all x, y and for all $\alpha \in [0, 1]$;

- *We know*: factors x_i are independent;
 - we know distribution of some of the factors;
 - for others, we know ranges $[x_j, \bar{x}_j]$ and means E_j .
- *Given*: a convex function $F \geq 0$ and a number $\varepsilon > 0$.
- *Objective*: find the smallest y_0 s.t. for all possible distributions, we have $y \leq y_0$ with the probability $\geq 1 - \varepsilon$.

57. Additional Property: Dependency is Non-Degenerate

- *Fact:* sometimes, we learn additional information about one of the factors x_j .
- *Example:* we learn that x_j actually belongs to a proper subinterval of the original interval $[\underline{x}_j, \bar{x}_j]$.
- *Consequence:* the class \mathcal{P} of possible distributions is replaced with $\mathcal{P}' \subset \mathcal{P}$.
- *Result:* the new value y'_0 can only decrease: $y'_0 \leq y_0$.
- *Fact:* if x_j is irrelevant for y , then $y'_0 = y_0$.
- *Assumption:* irrelevant variables been weeded out.
- *Formalization:* if we narrow down one of the intervals $[\underline{x}_j, \bar{x}_j]$, the resulting value y_0 decreases: $y'_0 < y_0$.

58. Formulation of the Problem

GIVEN: • $n, k \leq n, \varepsilon > 0$;

- a convex function $y = F(x_1, \dots, x_n) \geq 0$;
- $n - k$ cdfs $F_j(x)$, $k + 1 \leq j \leq n$;
- intervals $\mathbf{x}_1, \dots, \mathbf{x}_k$, values E_1, \dots, E_k ,

TAKE: all joint probability distributions on R^n for which:

- all x_i are independent,
- $x_j \in \mathbf{x}_j$, $E[x_j] = E_j$ for $j \leq k$, and
- x_j have distribution $F_j(x)$ for $j > k$.

FIND: the smallest y_0 s.t. for all such distributions,
 $F(x_1, \dots, x_n) \leq y_0$ with probability $\geq 1 - \varepsilon$.

WHEN: the problem is *non-degenerate* – if we narrow down one of the intervals \mathbf{x}_j , y_0 decreases.

59. Main Result and How We Can Use It

- *Result:* y_0 is attained when for each j from 1 to k ,

- $x_j = \underline{x}_j$ with probability $\underline{p}_j \stackrel{\text{def}}{=} \frac{\bar{x}_j - E_j}{\bar{x}_j - \underline{x}_j}$, and

- $x_j = \bar{x}_j$ with probability $\bar{p}_j \stackrel{\text{def}}{=} \frac{E_j - \underline{x}_j}{\bar{x}_j - \underline{x}_j}$.

- *Algorithm:*

- simulate these distributions for x_j , $j < k$;
- simulate known distributions for $j > k$;
- use the simulated values $x_j^{(s)}$ to find

$$y^{(s)} = F(x_1^{(s)}, \dots, x_n^{(s)});$$

- sort N values $y^{(s)}$: $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(N_i)}$;
- take $y_{(N_i \cdot (1-\varepsilon))}$ as y_0 .

60. Comment about Monte-Carlo Techniques

- *Traditional belief*: Monte-Carlo methods are inferior to analytical:
 - they are approximate;
 - they require large computation time;
 - simulations for *several* distributions, may mis-calculate the (desired) maximum over *all* distributions.
- *We proved*: the value corresponding to the selected distributions indeed provide the desired maximum value y_0 .
- *General comment*:
 - justified Monte-Carlo methods often lead to *faster* computations than analytical techniques;
 - example: multi-D integration – where Monte-Carlo methods were originally invented.

61. Comment about Non-Linear Terms

- *Reminder:* in the above formula $D_i = a_i + \sum_{j=1}^n a_{ij} \cdot x_j$, we ignored quadratic and higher order terms in the dependence of each path time D_i on parameters x_j .
- *In reality:* we may need to take into account some quadratic terms.
- *Idea behind possible solution:* it is known that the $\max_i D = \max_i D_i$ of convex functions D_i is convex.
- *Condition when this idea works:* when each dependence $D_i(x_1, \dots, x_k, \dots)$ is still convex.
- *Solution:* in this case,
 - the function D is still convex,
 - hence, our algorithm will work.

63. Combining Interval and Probabilistic Uncertainty: General Case

- *Problem:* there are many ways to represent a probability distribution.
- *Idea:* look for an objective.
- *Objective:* make decisions $E_x[u(x, a)] \rightarrow \max_a$.
- *Case 1:* smooth $u(x)$.
- *Analysis:* we have $u(x) = u(x_0) + (x - x_0) \cdot u'(x_0) + \dots$
- *Conclusion:* we must know moments to estimate $E[u]$.
- *Case of uncertainty:* interval bounds on moments.
- *Case 2:* threshold-type $u(x)$.
- *Conclusion:* we need cdf $F(x) = \text{Prob}(\xi \leq x)$.
- *Case of uncertainty:* p-box $[\underline{F}(x), \overline{F}(x)]$.

65. Successes (cont-d)

- *Easy cases*: $+$, $-$, product of independent x_i .
- *Example of a non-trivial case*: multiplication $y = x_1 \cdot x_2$, when we have no information about the correlation:

- $\underline{E} = \max(p_1 + p_2 - 1, 0) \cdot \bar{x}_1 \cdot \bar{x}_2 + \min(p_1, 1 - p_2) \cdot \bar{x}_1 \cdot \underline{x}_2 + \min(1 - p_1, p_2) \cdot \underline{x}_1 \cdot \bar{x}_2 + \max(1 - p_1 - p_2, 0) \cdot \underline{x}_1 \cdot \underline{x}_2$;
- $\bar{E} = \min(p_1, p_2) \cdot \bar{x}_1 \cdot \bar{x}_2 + \max(p_1 - p_2, 0) \cdot \bar{x}_1 \cdot \underline{x}_2 + \max(p_2 - p_1, 0) \cdot \underline{x}_1 \cdot \bar{x}_2 + \min(1 - p_1, 1 - p_2) \cdot \underline{x}_1 \cdot \underline{x}_2$,

where $p_i \stackrel{\text{def}}{=} (E_i - \underline{x}_i) / (\bar{x}_i - \underline{x}_i)$.

[General Problem of ...](#)[Cauchy Deviates Method](#)[Interval Arithmetic: ...](#)[Case Study: Chip Design](#)[Combining Interval ...](#)[Case Study: ...](#)[Case Study: Detecting ...](#)[Home Page](#)[Title Page](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 66 of 80](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

66. Example

- *Given:* $[\underline{x}_1, \bar{x}_1] = [\underline{x}_1, \bar{x}_2] = [-1, 1]$, $E_1 = E_2 = 0$.
- *Find:* the range of $E \stackrel{\text{def}}{=} E[x_1 \cdot x_2]$; solution:

$$p_1 = \frac{E_1 - \underline{x}_1}{\bar{x}_1 - \underline{x}_1} = \frac{0 - (-1)}{1 - (-1)} = \frac{1}{2} = 0.5,$$

- Similarly, $p_2 = 0.5$, so:

$$\underline{E} = \max(0.5 + 0.5 - 1, 0) \cdot 1 \cdot 1 + \min(0.5, 1 - 0.5) \cdot 1 \cdot (-1) +$$

$$\min(1 - 0.5, 0.5) \cdot (-1) \cdot 1 +$$

$$\max(1 - 0.5 - 0.5, 0) \cdot (-1) \cdot (-1) = -0.5 - 0.5 = -1;$$

$$\overline{E} = \min(0.5, 0.5) \cdot 1 \cdot 1 + \max(0.5 - 0.5, 0) \cdot 1 \cdot (-1) +$$

$$\max(0.5 - 0.5, 0) \cdot (-1) \cdot 1 +$$

$$\min(1 - 0.5, 1 - 0.5) \cdot (-1) \cdot (-1) = 0.5 + 0.5 = 1.$$

- *Solution:* the range is $[\underline{E}, \overline{E}] = [-1, 1]$.

73. Outlier Detection Under Interval Uncertainty: A Problem

- In some practical situations, we only have intervals $\mathbf{x}_i = [\underline{x}_i, \overline{x}_i]$.
- Different $x_i \in \mathbf{x}_i$ lead to different intervals $[L, U]$.
- A *possible* outlier: outside *some* k_0 -sigma interval.
- *Example*: structural integrity – not to miss a fault.
- A *guaranteed* outlier: outside *all* k_0 -sigma intervals.
- *Example*: before a surgery, we want to make sure that there is a micro-calcification.
- A value x is a possible outlier if $x \notin [\overline{L}, \underline{U}]$.
- A value x is a guaranteed outlier if $x \notin [\underline{L}, \overline{U}]$.
- *Conclusion*: to detect outliers, we must know the ranges of $L = E - k_0 \cdot \sigma$ and $U = E + k_0 \cdot \sigma$.

74. Outlier Detection Under Interval Uncertainty: A Solution

- *We need:* to detect outliers, we must compute the ranges of $L = E - k_0 \cdot \sigma$ and $U = E + k_0 \cdot \sigma$.
- *We know:* how to compute the ranges \mathbf{E} and $[\underline{\sigma}, \overline{\sigma}]$ for E and σ .
- *Possibility:* use interval computations to conclude that $L \in \mathbf{E} - k_0 \cdot [\underline{\sigma}, \overline{\sigma}]$ and $U \in \mathbf{E} + k_0 \cdot [\underline{\sigma}, \overline{\sigma}]$.
- *Problem:* the resulting intervals for L and U are *wider* than the actual ranges.
- *Reason:* E and σ use the same inputs x_1, \dots, x_n and are hence not independent from each other.
- *Practical consequence:* we miss some outliers.
- *Desirable:* compute *exact* ranges for L and U .
- *Application:* detecting outliers in gravity measurements.

76. Fuzzy Computations: A Problem

- *Given:* an algorithm $y = f(x_1, \dots, x_n)$ and n fuzzy numbers $\mu_i(x_i)$.
- *Compute:* $\mu(y) = \max_{x_1, \dots, x_n: f(x_1, \dots, x_n) = y} \min(\mu_1(x_1), \dots, \mu_n(x_n))$.
- *Motivation:* y is a possible value of $Y \leftrightarrow \exists x_1, \dots, x_n$ s.t. each x_i is a possible value of X_i and $f(x_1, \dots, x_n) = y$.
- *Details:* “and” is min, \exists (“or”) is max, hence
$$\mu(y) = \max_{x_1, \dots, x_n} \min(\mu_1(x_1), \dots, \mu_n(x_n), t(f(x_1, \dots, x_n) = y)),$$
where $t(\text{true}) = 1$ and $t(\text{false}) = 0$.

77. Fuzzy Computations: Reduction to Interval Computations

- *Problem (reminder):*
 - *Given:* an algorithm $y = f(x_1, \dots, x_n)$ and n fuzzy numbers X_i described by membership functions $\mu_i(x_i)$.
 - *Compute:* $Y = f(X_1, \dots, X_n)$, where Y is defined by Zadeh's extension principle:

$$\mu(y) = \max_{x_1, \dots, x_n: f(x_1, \dots, x_n) = y} \min(\mu_1(x_1), \dots, \mu_n(x_n)).$$

- *Idea:* represent each X_i by its α -cuts

$$X_i(\alpha) = \{x_i : \mu_i(x_i) \geq \alpha\}.$$

- *Advantage:* for continuous f , for every α , we have

$$Y(\alpha) = f(X_1(\alpha), \dots, X_n(\alpha)).$$

- *Resulting algorithm:* for $\alpha = 0, 0.1, 0.2, \dots, 1$ apply interval computations techniques to compute $Y(\alpha)$.

78. Proof of the Result about Chips

- Let us fix the optimal distributions for x_2, \dots, x_n ; then,

$$\text{Prob}(D \leq y_0) = \sum_{(x_1, \dots, x_n): D(x_1, \dots, x_n) \leq y_0} p_1(x_1) \cdot p_2(x_2) \cdot \dots$$

- So, $\text{Prob}(D \leq y_0) = \sum_{i=0}^N c_i \cdot q_i$, where $q_i \stackrel{\text{def}}{=} p_1(v_i)$.
- Restrictions: $q_i \geq 0$, $\sum_{i=0}^N q_i = 1$, and $\sum_{i=0}^N q_i \cdot v_i = E_1$.
- Thus, the worst-case distribution for x_1 is a solution to the following linear programming (LP) problem:

$$\begin{aligned} &\text{Minimize } \sum_{i=0}^N c_i \cdot q_i \text{ under the constraints } \sum_{i=0}^N q_i = 1 \text{ and} \\ &\sum_{i=0}^N q_i \cdot v_i = E_1, \quad q_i \geq 0, \quad i = 0, 1, 2, \dots, N. \end{aligned}$$

79. Proof of the Result about Chips (cont-d)

- *Minimize:* $\sum_{i=0}^N c_i \cdot q_i$ under the constraints $\sum_{i=0}^N q_i = 1$ and $\sum_{i=0}^N q_i \cdot v_i = E_1$, $q_i \geq 0$, $i = 0, 1, 2, \dots, N$.
- *Known:* in LP with $N + 1$ unknowns q_0, q_1, \dots, q_N , $\geq N + 1$ constraints are equalities.
- *In our case:* we have 2 equalities, so at least $N - 1$ constraints $q_i \geq 0$ are equalities.
- Hence, no more than 2 values $q_i = p_1(v_i)$ are non-0.
- If corresponding v or v' are in $(\underline{x}_1, \bar{x}_1)$, then for $[v, v'] \subset \mathbf{x}_1$ we get the same y_0 – in contradiction to non-degeneracy.
- Thus, the worst-case distribution is located at \underline{x}_1 and \bar{x}_1 .
- The condition that the mean of x_1 is E_1 leads to the desired formulas for \underline{p}_1 and \bar{p}_1 .
