1. Type-2-Motivated Approach

- An expert describes his/her opinion about a quantity by using imprecise (“fuzzy”) natural language words.
- Example: “small”, “large”, etc.
- Each of these words provides a rather crude description of the corresponding quantity.
- A natural way to refine this description is to assign degrees to which the observed quantity fits each word.
- For example, an expert can say that the value is reasonable small, but to some extent it is medium.
- In this refined description, we represent each quantity by a tuple of the corresponding degrees.

2. Challenge

- Need for data processing:
 - we have such a tuple-based information about several quantities x_1, \dots, x_m , and
 - we know that another quantity y is related to x_i by a known relation $y = f(x_1, \dots, x_m)$;
 - it is desirable to come up with a resulting tuple-based description of y .
- It turns out that a seemingly natural idea for computing such a tuple does not work.
- This idea can be modified so that it can be used.

3. How to Implement the Above Approach

- We have degree d_i assigned to the i -th word, with membership function $\mu_i(x)$.
- Based on this information, what is then the degree $\mu_d(x)$ to which x is a possible value?
 - either the quantity is described by the 1st word, and this word is adequate for x ; degree $\min(d_1, \mu_1(x))$;
 - here, we interpret “and” as \min ;
 - or the quantity is described by the 2nd word, and this word is adequate for x ; the degree $\min(d_2, \mu_2(x))$;
 - etc.
- We interpret “or” as \max .
- So, the resulting degree is $\mu_d(x) = \max_i \min(d_i, \mu_i(x))$.

4. How to Implement the Above Approach (cont-d)

- Simplest membership functions:

- The resulting degree $\mu_d(x) = \max_i \min(d_i, \mu_i(x))$:

5. A Seemingly Natural Implementation

- We want to be able to transform a general membership function $\mu(x)$ into a tuple of degrees $d = (d_1, \dots, d_n)$.
- Our hope is that for the f-n $\mu_d(x) = \max_i \min(d_i, \mu_i(x))$, we get back the degrees d_i .
- Seemingly natural idea: $\mu(x)$ corresponds to the i -th word if:
 - either a value x is in agreement with $\mu(x)$ and with this word;
 - or a value x' is in agreement with $\mu(x)$ and with this word;
 - etc.
- The resulting degree is $\max_x \min(\mu(x), \mu_i(x))$.

6. Limitations of a Seemingly Natural Implementation

- *Idea:* estimate d_i as $\max_x \min(\mu(x), \mu_i(x))$.
- Our hope is that for the f-n $\mu_d(x) = \max_i \min(d_i, \mu_i(x))$, we get back the degrees d_i .
- *Problem:* for the basic function $\mu(x) = \mu_1(x)$ corr. to $d = (1, 0, \dots, 0)$, we do not get back $(1, 0, \dots, 0)$:

- Specifically, for $\mu(x) = \mu_1(x)$, we get

$$\max_x \min(\mu(x), \mu_2(x)) = 0.5 \neq d_2 = 0.$$

7. Towards a Possible Solution

- Intersection leads to $\max_x \min(\mu(x), \mu_i(x)) \neq d_i$.
- So let us remove the intersecting parts from the membership function before applying the above formula:

- we compute “reduced” basic functions

$$\mu'_i(x) = \max(0, \mu_i(x) - \max(\mu_{i-1}(x), \mu_{i+1}(x)));$$

- we also compute the “reduced” membership function

$$\mu'(x) = \max(0, \mu(x) - \max(\mu_{i-1}(x), \mu_{i+1}(x)));$$

- then, we compute the degrees based on these reduced functions, as

$$\tilde{d}_i = \max_x (\min(\mu'(x), \mu'_i(x))).$$

8. This Idea Does Lead to a Possible Solution

- *Reminder:* we compute $\tilde{d}_i = \max_x(\min(\mu'(x), \mu'_i(x)))$, where

$$\mu'_i(x) = \max(0, \mu_i(x) - \max(\mu_{i-1}(x), \mu_{i+1}(x)));$$

$$\mu'(x) = \max(0, \mu(x) - \max(\mu_{i-1}(x), \mu_{i+1}(x)));$$

- Interesting fact: if we apply this to the function $\mu_d(x) = \max_i \min(d_i, \mu_i(x))$, we do get back the degrees d_i :

$$\tilde{d}_i = d_i.$$
