## 1. Main Objective

- The main objective of this tutorial is to describe theoretical foundations for modern intelligent techniques.
- The emphasis will be on:
  - foundations of fuzzy techniques,
  - foundations of neural networks (in particular, deep neural networks), and
  - foundations of quantum computing.

*Main Objective*

*Time to Gather Stones*

*Case Studies*

## 2. Time to Gather Stones

- Many heuristic methods have been developed in intelligent computing.
- Some of them work well, some don't work so well.
- And promising techniques – that work well – often benefit from trial-and-error tuning.
- It is great to know and use all these techniques.
- It is also time to analyze why some technique work well and some don't.
- Following the Biblical analogy, we have gone through the time when we cast away stones in all directions.
- It is now time to gather stones, time to try to find the common patterns behind the successful ideas.
- Hopefully, in the future, this analysis will help.

### 3. Case Studies

- In this tutorial, we will concentrate on three classes of empirically successful semi-heuristic methods.
- Fuzzy techniques, techniques for translating:
  - expert knowledge described in terms of imprecise (“fuzzy”) natural-language words like “small”
  - into precise numerical strategies.
- Neural networks (in particular, deep neural networks), techniques for learning a dependence from examples.
- Quantum computing, techniques that use quantum effects to make computations faster and more reliable.

## 4. Fuzzy Techniques Are Needed

- In many application areas, we have experts whose experience we would like to capture.
- Often, experts' rules use imprecise (“fuzzy”) words from natural language, like “small”, “large”, etc.
- To formalize these rules, L. Zadeh proposed special *fuzzy techniques*.
- A usual application of fuzzy techniques consists of the following three stages:
  - 1) reformulate expert knowledge in computer understandable terms – i.e., as numbers;
  - 2) process these numbers to come up with the degrees to which different actions are reasonable;
  - 3) if needed, “defuzzify” this “fuzzy” recommendation into an exact strategy.

## 5. First Stage of Fuzzy Technique

- In the first stage, we formalize the imprecise terms used by the experts, such as “small”, “hot”, and “fast”.
- Each such term is described by assigning,
  - to different possible values  $x$ ,
  - a degree  $\mu(x)$  to which  $x$  satisfies this term (e.g., to which  $x$  is small).
- Some values  $\mu(x)$  are obtained by asking the expert.
- However, there are infinitely many real numbers  $x$ , and we can only ask a finite number of questions,
- Thus, we need to perform *interpolation* to estimate the degrees  $\mu(x)$  for intermediate values  $x$ .
- The result  $\mu(x)$  is called the *membership function*.

## 6. Second Stage of Fuzzy Techniques: “And”- and “Or”-Operations

- Many expert rules involve several conditions.
- *Example:* a doctor will prescribe a certain medicine if the fever is high *and* blood pressure is normal.
- To handle such rules, we need to be able to transform:
  - the degrees  $a = d(A)$  and  $b = d(B)$  of individual conditions  $A$  and  $B$
  - into a degree of confidence in the composite statement  $A \& B$ .
- The corresponding estimate  $f_{\&}(a, b)$  is known as an “*and*”-operation, or, alternatively, as a *t-norm*.
- Similarly, we need an “*or*”-operation  $f_{\vee}(a, b)$  (*t-conorm*) and a *negation operation*  $f_{-}(a)$ .

## 7. Third Stage of Fuzzy Techniques: Defuzzification

- After performing the first two stages,
  - for the given input  $x$  and for all possible control values  $u$ ,
  - we get a degree  $\mu(u)$  to which this control value is reasonable to apply.
- Sometimes, we want to use this expert knowledge in an automated system.
- In this case, we need to transform this membership function  $\mu(u)$  into a single value  $\bar{u}$ .

## 8. Versions of Fuzzy Techniques

- There are many different membership functions  $\mu(x)$ , “and”- and “or”-operations, and defuzzifications.
- In practice, a few choices are the most efficient:
  - *trapezoid*  $\mu(x)$ : start with 0, linearly got to 1, stay at 1, then linearly decrease to 0;
  - $f_{\&}(a, b) = \min(a, b)$  or  $f_{\&}(a, b) = a \cdot b$ ;
  - $f_{\vee}(a, b) = \max(a, b)$  or  $f_{\vee}(a, b) = a + b - a \cdot b$ ;
  - negation operation  $f_{-}(a) = 1 - a$ ; and
  - *centroid defuzzification*  $\bar{u} = \frac{\int u \cdot \mu(u) du}{\int \mu(u) du}$ .
- Similarly, for interval-valued case, both lower and upper membership functions are usually trapezoidal.
- We show that all these choices can be explained by the use of the simplest (linear) interpolation.

## 9. Linear Interpolation Is the Simplest

- Interpolation means that we find a function that attains known values at given points.
- The simplest possible non-constant functions are linear functions.
- They are also the least sensitive to uncertainty in  $x$ .
- We want the vector  $e \stackrel{\text{def}}{=} (e_1, \dots, e_k)$  of values  $e_i \stackrel{\text{def}}{=} f'(x_i)$  to be as close to the ideal point  $(0, \dots, 0)$  as possible.
- The distance between the vector  $e$  and the 0 point is equal to  $\sqrt{e_1^2 + \dots + e_k^2}$ .
- Minimizing the distance is equivalent to minimizing its square  $e_1^2 + \dots + e_k^2 = (f'(x_1))^2 + \dots + (f'(x_k))^2$ .
- This is the usual *Least Squares* method.

[Main Objective](#)[Time to Gather Stones](#)[Case Studies](#)[Fuzzy Case](#)[Neural Network Case](#)[Quantum Computing](#)[Proofs \(if time allows\)](#)[Home Page](#)[Title Page](#)[<<](#)[>>](#)[<](#)[>](#)[Page 11 of 147](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

## 10. Linear Interpolation (cont-d)

- In the continuous case, we get an integral  $\int (f'(x))^2 dx$ .
- Minimizing this interval, we get  $f''(x) = 0$ , so  $f(x)$  is linear.
- If we know that  $y_1 = f(x_1)$  and  $y_2 = f(x_2)$ , then these two values uniquely determine a linear function:

$$f(x) = f(x_1) + \frac{y_2 - y_1}{x_2 - x_1} \cdot (x - x_1).$$

- We will show that this simplest (linear) interpolation explains all usual choices of fuzzy techniques.

## 11. Explaining Trapezoid Membership Functions

- For each property like “small”:
  - first, there are some values which are definitely not small (e.g., negative ones),
  - then some values which are small to some extent;
  - then, we have an interval of values which are definitely small;
  - this is followed by values which are somewhat small;
  - finally, we get values which are absolutely not small.
- Let us denote the values (“thresholds”) that separate these regions by  $t_1$ ,  $t_2$ ,  $t_3$ , and  $t_4$ .
- Then:  $\mu(x) = 0$  for  $x \leq t_1$ ;  $\mu(x) = 1$  for  $t_2 \leq x \leq t_3$ ; and  $\mu(x) = 0$  for  $x \geq t_4$ .
- Linear interpolation indeed leads to trapezoid functions.

## 12. Explaining $f_{\&}(a, b) = a \cdot b$

- If one of the component statements  $A$  is false, then the composite statement  $A \& B$  is also false:  $f_{\&}(0, b) = 0$ .
- If  $A$  is absolutely true, then our belief in  $A \& B$  is equivalent to our degree of belief in  $B$ :  $f_{\&}(1, b) = b$ .
- Let us fix  $b$  and consider a function  $F_b(a) \stackrel{\text{def}}{=} f_{\&}(a, b)$  that maps  $a$  into the value  $f_{\&}(a, b)$ .
- We know that  $F_b(0) = 0$  and  $F_b(1) = b$ .
- Linear interpolation leads to  $F_b(a) = a \cdot b$ , i.e., to the algebraic product  $f_{\&}(a, b) = a \cdot b$ .
- Please note that:
  - while the resulting operation is commutative and associative,
  - we did not require commutativity or associativity;
  - all we required was linear interpolation.

### 13. What If We Additionally Require That $A \& A$ is Equivalent to $A$

- Another intuitive property of “and” is that for every  $B$ , “ $B$  and  $B$ ” means the same as  $B$ :  $f_{\&}(b, b) = b$ .
- We know that  $F_b(0) = f_{\&}(0, b) = 0$  and that  $F_b(b) = f_{\&}(b, b) = b$ .
- Thus, on the interval  $[0, b]$ , linear interpolation leads to  $F_b(a) = a$ , i.e., to  $f_{\&}(a, b) = a$ .
- From  $F_b(b) = b$  and  $F_b(1) = f_{\&}(1, b) = b$ , we conclude that  $f_{\&}(a, b) = F_b(a) = b$  for all  $a \in [b, 1]$ ; so:
  - $f_{\&}(a, b) = a$  when  $a \leq b$  and
  - $f_{\&}(a, b) = b$  when  $b \leq a$ .
- Thus,  $f_{\&}(a, b) = \min(a, b)$ .

## 14. Linear Interpolation Explains the Usual Choice of t-Conorms

- If  $A$  is absolutely true, then  $A \vee B$  is also absolutely true:  $f_{\vee}(a, b) = f_{\vee}(1, b) = 1$ .
- If  $A$  is absolutely false, then our belief in  $A \vee B$  is equivalent to our degree of belief in  $B$ :  $f_{\vee}(0, b) = b$ .
- For  $G_b(a) \stackrel{\text{def}}{=} f_{\vee}(a, b)$ , we get  $G_b(0) = b$  and  $G_b(1) = 1$ .
- Linear interpolation leads to  $G_b(a) = b + a \cdot (1 - b)$ , i.e., to the algebraic sum  $f_{\vee}(a, b) = a + b - a \cdot b$ .
- Note that:
  - while the resulting operation is commutative and associative,
  - we did not require commutativity or associativity,
  - all we required was linear interpolation.

## 15. What If We Additionally Require That $A \vee A$ is Equivalent to $A$

- Another intuitive property of “or” is that for every  $B$ , “ $B$  or  $B$ ” means the same as  $B$ :  $f_{\vee}(b, b) = b$ .
- We know that  $G_b(0) = f_{\vee}(0, b) = b$  and that  $G_b(b) = f_{\vee}(b, b) = b$ .
- Thus, for  $a \in [0, b]$ , linear interpolation leads to  $G_b(a) = b$ , i.e., to  $f_{\&}(a, b) = b$ .
- From  $G_b(b) = b$  and  $G_b(1) = f_{\vee}(1, b) = 1$ , we conclude that  $f_{\&}(a, b) = G_b(a) = a$  for all  $a \in [b, 1]$ ; so:
  - $f_{\vee}(a, b) = b$  when  $a \leq b$  and
  - $f_{\vee}(a, b) = a$  when  $b \leq a$ .
- Thus,  $f_{\vee}(a, b) = \max(a, b)$ .

## 16. Simple Linear Interpolation Explains the Usual Choice of Negation Operations

- For the 2-valued logic, with truth values 1 (“true”) and 0 (“false”), the negation operation is easy:
  - the negation of “false” is “true”:  $f_{-}(0) = 1$ , and
  - the negation of “true” is “false”:  $f_{-}(1) = 0$ .
- We want to extend this operation from the 2-valued set  $\{0, 1\}$  to the whole interval  $[0, 1]$ .
- Linear interpolation leads to  $f_{-}(a) = 1 - a$ .
- This is exactly the most frequently used negation operation in fuzzy logic.

## 17. Simple Linear Interpolation Explains the Usual Choice of Defuzzification

- The desired control  $\bar{u}$  should be close to reasonable control values  $u$ :  $\bar{u} \approx u$ .
- We have different possible control values  $u$ .
- Let us start with a simplified situation in which we have finitely many equally values  $u_1, \dots, u_k$ .
- In this case, we want to find the values  $\bar{u}$  for which  $\bar{u} \approx u_1, \bar{u} \approx u_2, \dots, \bar{u} \approx u_k$ .
- Since the values  $u_i$  are different, we cannot get the exact equality in all  $k$  cases:  $e_k \stackrel{\text{def}}{=} \bar{u} - u_k \neq 0$ .
- We want the vector  $e \stackrel{\text{def}}{=} (e_1, \dots, e_k)$  to be as close to the ideal point  $(0, \dots, 0)$  as possible.
- The distance between the vector  $e$  and the 0 point is equal to  $\sqrt{e_1^2 + \dots + e_k^2}$ .

## 18. Defuzzification (cont-d)

- Minimizing the distance is equivalent to minimizing its square  $e_1^2 + \dots + e_k^2 = (\bar{u} - u_1)^2 + \dots + (\bar{u} - u_k)^2$ .
- This is the usual *Least Squares* method.
- In the continuous case, we get an integral  $\int (\bar{u} - u)^2 du$ .
- This method works well if all the values  $u$  are equally possible.
- In reality, different values  $u$  have different degrees of possibility  $\mu(u)$ .
- If  $u$  is fully possible ( $\mu(u) = 1$ ), we should keep the term  $(\bar{u} - u)^2$  in the sum.
- If  $u$  is completely impossible ( $\mu(u) = 0$ ), we should not consider this term at all.

## 19. Defuzzification: Result

- In general:
  - instead of simply adding the squares,
  - we first multiply each square by a weight  $w(\mu(u))$  depending on  $\mu(u)$ , so that  $w(1) = 1$  and  $w(0) = 0$ .
- Thus, we minimize  $\int w(\mu(u)) \cdot (\bar{u} - u)^2 du$ .
- Linear interpolation leads to  $w(\mu) = \mu$ , so we minimize

$$\int \mu(u) \cdot (\bar{u} - u)^2 du.$$

- Differentiating this expression with respect to  $\bar{u}$  and equating the derivative to 0, we conclude that

$$\bar{u} = \frac{\int u \cdot \mu(u) du}{\int \mu(u) du}.$$

- So, simple linear interpolation explains the usual choice of centroid defuzzification.

## 20. Fuzzy Part: Conclusion

- In many real-life situations, we need to process expert knowledge.
- Experts often describe their knowledge by using imprecise (“fuzzy”) terms from natural language.
- For processing such knowledge, Zadeh invented fuzzy techniques.
- Most efficient practical applications of fuzzy techniques use a specific combination of fuzzy techniques:
  - triangular or trapezoid membership functions,
  - simple t-norms (min or product),
  - simple t-conorms (max or algebraic sum), and
  - centroid defuzzification.
- For each of these choices, there exists an explanation of why this particular choice is efficient.

## 21. Conclusion (cont-d)

- Most efficient applications of fuzzy techniques use:
  - triangular or trapezoid membership functions,
  - simple t-norms (min or product),
  - simple t-conorms (max or algebraic sum), and
  - centroid defuzzification.
- For each of these choices, there exists an explanation of why this particular choice is efficient.
- The usual explanations, however, are different for different techniques.
- We show that all these choices can be explained by the use of the simplest (linear) interpolation.
- In our opinion, such a uniform explanation makes the resulting choices easier to accept (and easier to teach).

## 22. Why Traditional Neural Networks: (Sanitized) History

- How do we make computers think?
- To make machines that fly it is reasonable to look at the creatures that know how to fly: the birds.
- To make computers think, it is reasonable to analyze how we humans think.
- On the biological level, our brain processes information via special cells called ]it neurons.
- Somewhat surprisingly, in the brain, signals are electric – just as in the computer.
- The main difference is that in a neural network, signals are sequence of identical pulses.

## 23. Why Traditional NN: (Sanitized) History

- The intensity of a signal is described by the frequency of pulses.
- A neuron has many inputs (up to  $10^4$ ).
- All the inputs  $x_1, \dots, x_n$  are combined, with some loss, into a frequency  $\sum_{i=1}^n w_i \cdot x_i$ .
- Low inputs do not active the neuron at all, high inputs lead to largest activation.

- The output signal is a non-linear function

$$y = f \left( \sum_{i=1}^n w_i \cdot x_i - w_0 \right).$$

- In biological neurons,  $f(x) = 1/(1 + \exp(-x))$ .
- Traditional neural networks emulate such biological neurons.

## 24. Why Traditional Neural Networks: Real History

- At first, researchers ignored non-linearity and only used linear neurons.
- They got good results and made many promises.
- The euphoria ended in the 1960s when MIT's Marvin Minsky and Seymour Papert published a book.
- Their main result was that a composition of linear functions is linear (I am not kidding).
- This ended the hopes of original schemes.
- For some time, neural networks became a bad word.
- Then, smart researchers came us with a genius idea: let's make neurons non-linear.
- This revived the field.

## 25. Traditional Neural Networks: Main Motivation

- One of the main motivations for neural networks was that computers were slow.
- Although human neurons are much slower than CPU, the human processing was often faster.
- So, the main motivation was to make data processing faster.
- The idea was that:
  - since we are the result of billion years of ever improving evolution,
  - our biological mechanics should be optimal (or close to optimal).

## 26. How the Need for Fast Computation Leads to Traditional Neural Networks

- To make processing faster, we need to have many fast processing units working in parallel.
- The fewer layers, the smaller overall processing time.
- In nature, there are many fast linear processes – e.g., combining electric signals.
- As a result, linear processing (L) is faster than non-linear one.
- For non-linear processing, the more inputs, the longer it takes.
- So, the fastest non-linear processing (NL) units process just one input.
- It turns out that two layers are not enough to approximate any function.

## 27. Why One or Two Layers Are Not Enough

- With 1 linear (L) layer, we only get linear functions.
- With one nonlinear (NL) layer, we only get functions of one variable.
- With L→NL layers, we get  $g\left(\sum_{i=1}^n w_i \cdot x_i - w_0\right)$ .
- For these functions, the level sets  $f(x_1, \dots, x_n) = \text{const}$  are planes  $\sum_{i=1}^n w_i \cdot x_i = c$ .
- Thus, they cannot approximate, e.g.,  $f(x_1, x_2) = x_1 \cdot x_2$  for which the level set is a hyperbola.
- For NL→L layers, we get  $f(x_1, \dots, x_n) = \sum_{i=1}^n f_i(x_i)$ .
- For all these functions,  $d \stackrel{\text{def}}{=} \frac{\partial^2 f}{\partial x_1 \partial x_2} = 0$ , so we also cannot approximate  $f(x_1, x_2) = x_1 \cdot x_2$  with  $d = 1 \neq 0$ .

## 28. Why Three Layers Are Sufficient: Newton's Prism and Fourier Transform

- In principle, we can have two 3-layer configurations:  
 $L \rightarrow NL \rightarrow L$  and  $NL \rightarrow L \rightarrow NL$ .

- Since  $L$  is faster than  $NL$ , the fastest is  $L \rightarrow NL \rightarrow L$ :

$$y = \sum_{k=1}^K W_k \cdot f_k \left( \sum_{i=1}^n w_{ki} \cdot x_i - w_{k0} \right) - W_0.$$

- Newton showed that a prism decomposes white light (or any light) into elementary colors.
- In precise terms, elementary colors are sinusoids

$$A \cdot \sin(w \cdot t) + B \cdot \cos(w \cdot t).$$

- Thus, every function can be approximated, with any accuracy, as a linear combination of sinusoids:

$$f(x_1) \approx \sum_k (A_k \cdot \sin(w_k \cdot x_1) + B_k \cdot \cos(w_k \cdot x_1)).$$

## 29. Why Three Layers Are Sufficient (cont-d)

- Newton's prism result:

$$f(x_1) \approx \sum_k (A_k \cdot \sin(w_k \cdot x_1) + B_k \cdot \cos(w_k \cdot x_1)).$$

- This result was theoretically proven later by Fourier.
- For  $f(x_1, x_2)$ , we get a similar expression for each  $x_2$ , with  $A_k(x_2)$  and  $B_k(x_2)$ .
- We can similarly represent  $A_k(x_2)$  and  $B_k(x_2)$ , thus getting products of sines, and it is known that, e.g.:

$$\cos(a) \cdot \cos(b) = \frac{1}{2} \cdot (\cos(a + b) + \cos(a - b)).$$

- Thus, we get an approximation of the desired form with  $f_k = \sin$  or  $f_k = \cos$ :

$$y = \sum_{k=1}^K W_k \cdot f_k \left( \sum_{i=1}^n w_{ki} \cdot x_i - w_{k0} \right).$$

### 30. Which Activation Functions $f_k(z)$ Should We Choose

- A general 3-layer NN has the form:

$$y = \sum_{k=1}^K W_k \cdot f_k \left( \sum_{i=1}^n w_{ki} \cdot x_i - w_{k0} \right) - W_0.$$

- Biological neurons use  $f(z) = 1/(1 + \exp(-z))$ , but shall we simulate it?
- Simulations are not always efficient.
- E.g., airplanes have wings like birds but they do not flap them.
- Let us analyze this problem theoretically.
- There is always some noise  $c$  in the communication channel.
- So, we can consider either the original signals  $x_i$  or denoised ones  $x_i - c$ .

### 31. Which $f_k(z)$ Should We Choose (cont-d)

- The results should not change if we perform a full or partial denoising  $z \rightarrow z' = z - c$ .
- Denoising means replacing  $y = f(z)$  with  $y' = f(z - c)$ .
- So,  $f(z)$  should not change under shift  $z \rightarrow z - c$ .
- Of course,  $f(z)$  cannot remain the same: if  $f(z) = f(z - c)$  for all  $c$ , then  $f(z) = \text{const}$ .
- The idea is that once we re-scale  $x$ , we should get the same formula after we apply a natural  $y$ -re-scaling  $T_c$ :

$$f(x - c) = T_c(f(x)).$$

- Linear re-scalings are natural: they corresponding to changing units and starting points (like C to F).

## 32. Which Transformations Are Natural?

- An inverse  $T_c^{-1}$  to a natural re-scaling  $T_c$  should also be natural.
- A composition  $y \rightarrow T_c(T_{c'}(y))$  of two natural re-scalings  $T_c$  and  $T_{c'}$  should also be natural.
- In mathematical terms, natural re-scalings form a *group*.
- For practical purposes, we should only consider re-scaling determined by finitely many parameters.
- So, we look for a finite-parametric group containing all linear transformations.

### 33. A Somewhat Unexpected Approach

- N. Wiener, in *Cybernetics*, notices that when we approach an object, we have distinct phases:
  - first, we see a blob (the image is invariant under all transformations);
  - then, we start distinguishing angles from smooth but not sizes (projective transformations);
  - after that, we detect parallel lines (affine transformations);
  - then, we detect relative sizes (similarities);
  - finally, we see the exact shapes and sizes.
- Are there other transformation groups?
- Wiener argued: if there are other groups, after billions years of evolutions, we would use them.
- So he conjectured that there are no other groups.

## 34. Wiener Was Right

- Wiener's conjecture was indeed proven in the 1960s.
- In 1-D case, this means that all our transformations are fractionally linear:

$$f(z - c) = \frac{A(c) \cdot f(z) + B(c)}{C(c) \cdot f(z) + D(c)}.$$

- For  $c = 0$ , we get  $A(0) = D(0) = 1$ ,  $B(0) = C(0) = 0$ .
- Differentiating the above equation by  $c$  and taking  $c = 0$ , we get a differential equation for  $f(z)$ :

$$-\frac{df}{dz} = (A'(0) \cdot f(z) + B'(0)) - f(z) \cdot (C'(0) \cdot f(z) + D'(0)).$$

- So, 
$$\frac{df}{C'(0) \cdot f^2 + (A'(0) - C'(0)) \cdot f + B'(0)} = -dz.$$
- Integrating, we indeed get  $f(z) = 1/(1 + \exp(-z))$  (after an appropriate linear re-scaling of  $z$  and  $f(z)$ ).

## 35. How to Train Traditional Neural Networks: Main Idea

- *Reminder:* a 3-layer neural network has the form:

$$y = \sum_{k=1}^K W_k \cdot f \left( \sum_{i=1}^n w_{ki} \cdot x_i - w_{k0} \right) - W_0.$$

- We need to find the weights that best described observations  $(x_1^{(p)}, \dots, x_n^{(p)}, y^{(p)})$ ,  $1 \leq p \leq P$ .
- We find the weights that minimize the mean square approximation error  $E \stackrel{\text{def}}{=} \sum_{p=1}^P \left( y^{(p)} - y_{NN}^{(p)} \right)^2$ , where

$$y^{(p)} = \sum_{k=1}^K W_k \cdot f \left( \sum_{i=1}^n w_{ki} \cdot x_i^{(p)} - w_{k0} \right) - W_0.$$

- The simplest minimization algorithm is gradient descent:  $w_i \rightarrow w_i - \lambda \cdot \frac{\partial E}{\partial w_i}$ .

## 36. Towards Faster Differentiation

- To achieve high accuracy, we need many neurons.
- Thus, we need to find many weights.
- To apply gradient descent, we need to compute all partial derivatives  $\frac{\partial E}{\partial w_i}$ .
- Differentiating a function  $f$  is easy:
  - the expression  $f$  is a sequence of elementary steps,
  - so we take into account that  $(f \pm g)' = f' \pm g'$ ,  $(f \cdot g)' = f' \cdot g + f \cdot g'$ ,  $(f(g))' = f'(g) \cdot g'$ , etc.
- For a function that takes  $T$  steps to compute, computing  $f'$  thus takes  $c_0 \cdot T$  steps, with  $c_0 \leq 3$ .
- However, for a function of  $n$  variables, we need to compute  $n$  derivatives.
- This would take time  $n \cdot c_0 \cdot T \gg T$ : this is too long.

## 37. Faster Differentiation: Backpropagation

- Idea:
  - instead of starting from the variables,
  - start from the last step, and compute  $\frac{\partial E}{\partial v}$  for all intermediate results  $v$ .
- For example, if the very last step is  $E = a \cdot b$ , then  $\frac{\partial E}{\partial a} = b$  and  $\frac{\partial E}{\partial b} = a$ .
- At each step  $y$ , if we know  $\frac{\partial E}{\partial v}$  and  $v = a \cdot b$ , then  $\frac{\partial E}{\partial a} = \frac{\partial E}{\partial v} \cdot b$  and  $\frac{\partial E}{\partial b} = \frac{\partial E}{\partial v} \cdot a$ .
- At the end, we get all  $n$  derivatives  $\frac{\partial E}{\partial w_i}$  in time
$$c_0 \cdot T \ll c_0 \cdot T \cdot n.$$
- This is known as *backpropagation*.

## 38. Beyond Traditional NN

- Nowadays, computer speed is no longer a big problem.
- What *is* a problem is *accuracy*: even after thousands of iterations, the NNs do not learn well.
- So, instead of computation speed, we would like to maximize learning accuracy.
- We can still consider L and NL elements.
- For the same number of variables  $w_i$ , we want to get more accurate approximations.
- For given number of variables, and given accuracy, we get  $N$  possible combinations.
- If all combinations correspond to different functions, we can implement  $N$  functions.
- However, if some combinations lead to the same function, we implement fewer different functions.

## 39. From Traditional NN to Deep Learning

- For a traditional NN with  $K$  neurons, each of  $K!$  permutations of neurons retains the resulting function.
- Thus, instead of  $N$  functions, we only implement

$$\frac{N}{K!} \ll N \text{ functions.}$$

- Thus, to increase accuracy, we need to minimize the number  $K$  of neurons in each layer.
- To get a good accuracy, we need many parameters, thus many neurons.
- Since each layer is small, we thus need many layers.
- This is the *main idea* behind *deep learning*.

## 40. Empirical Formulas Behind Deep Learning Successes and How They Can Be Justified

- The general idea of deep learning is natural.
- However, any specific formulas that lead to deep learning successes are purely empirical.
- These formulas need to be explained.
- In this part of the tutorial:
  - we list such formulas, and
  - we briefly mention how the corresponding formulas can be explained.

## 41. Rectified Linear Neurons

- Traditional neural networks use complex nonlinear neurons.
- On contrast, deep networks utilize *rectified linear neurons* with the activation function

$$s_0(z) = \max(0, z).$$

- Our explanation is that:
  - this activation function is invariant under re-scaling (changing of the measuring unit)  $z \rightarrow \lambda \cdot x$ ;
  - moreover, it is, in effect, the only activation function which is this invariant, and
  - it is the only activation f-n optimal with respect to any scale-invariant optimality criterion.

## 42. Combining Several Results

- To speed up the training, the current deep learning algorithms use dropout techniques:
  - they train several sub-networks on different portions of data, and then
  - “average” the results.
- A natural idea is to use arithmetic mean for this “averaging”.
- However, empirically, geometric mean works much better.
- How to explain this empirical efficiency?
- It turns out that
  - this choice is scale-invariant – and,
  - in effect, it is the only scale-invariant choice.

## 43. Softmax

- In deep learning:
  - instead of selecting an alternative for which the objective function  $f(x)$  is the largest possible,
  - we use so-called *softmax* – i.e., select each alternative  $x$  with probability proportional to  $\exp(\alpha \cdot f(x))$ .
- In general, we could select any increasing function  $F(z)$  and select probabilities proportional to  $F(f(x))$ .
- So why exponential function is the most successful?

## 44. Softmax: Explanation

- When we use softmax, the probabilities do not change if we simply shift all the values  $f(x)$ .
- I.e., if we change them to  $f(x) + c$  for some  $c$ .
- This shift does not change the original optimization problem.
- Moreover, exponential functions are the only ones which lead to such shift-invariant selection.
- The exponential functions are only ones which optimal under a shift-invariant optimality criterion.

## 45. Need for Convolutional Neural Networks

- In many practical situations, the available data comes:
  - in terms of *time series* – when we have values measured at equally spaced time moments – or
  - in terms of an *image* – when we have data corresponding to a grid of spatial locations.
- Neural networks for processing such data are known as *convolutional neural networks*.

## 46. Need for Pooling

- We want to decrease the distortions caused by measurement errors.
- For that, we take into account that usually, the actual values at nearby points in time or space are close to each other.
- As a result,
  - instead of using the measurement-distorted value at each point,
  - we can take into account that values at nearby points are close, and
  - combine (“pool together”) these values into a single more accurate estimate.

## 47. Which Pooling Techniques Work Better: Empirical Results

- In principle, we can have many different pooling algorithms.
- It turns out that empirically, in general, the most efficient pooling algorithm is *max-pooling*:

$$a = \max(a_1, \dots, a_m).$$

- The next efficient is *average pooling*, when we take the arithmetic average  $a = \frac{a_1 + \dots + a_m}{m}$ .
- In this tutorial, we provide a theoretical explanation for this empirical observation.
- Namely, we prove that max and average poolings are indeed optimal.

[Main Objective](#)[Time to Gather Stones](#)[Case Studies](#)[Fuzzy Case](#)[Neural Network Case](#)[Quantum Computing](#)[Proofs \(if time allows\)](#)[Home Page](#)[Title Page](#)[◀](#)[▶](#)[◀](#)[▶](#)[Page 50 of 147](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

## 48. Pooling: Towards a Precise Definition

- Based on  $m$  values  $a_1, \dots, a_m$ , we want to generate a single value  $a$ .
- In the case of arithmetic average, we select  $a$  for which  $a_1 + \dots + a_m = a + \dots + a$  ( $m$  times).
- In general, pooling means that:
  - we select some combination operation  $*$  and
  - we then select the value  $a$  for which  $a_1 * \dots * a_m = a * \dots * a$  ( $m$  times).
- For example:
  - if, as a combination operation, we select  $\max(a, b)$ ,
  - then the corresponding condition  $\max(a_1, \dots, a_n) = \max(a, \dots, a) = a$  describes the max-pooling.
- From this viewpoint, selecting pooling means selecting an appropriate combination operation.

## 49. Natural Properties of a Combination Operation

- The combination operation transforms:
  - two non-negative values – such as intensity of an image at a given location
  - into a single non-negative value.
- The result of applying this operation should not depend on the order in which we combine the values.
- Thus, we should have  $a * b = b * a$  (commutativity) and  $a * (b * c) = (a * b) * c$  (associativity).

## 50. What Does It Mean to Have an Optimal Pooling?

- Optimality means that on the set of all possible combination operations, we have a preference relation  $\preceq$ .
- $A \preceq B$  means that the operation  $B$  is better than (or of the same quality as) the operation  $A$ .
- This relation should be transitive:
  - if  $C$  is better than  $B$  and  $B$  is better than  $A$ ,
  - then  $C$  should be better than  $A$ .
- An operation  $A$  is optimal if it is better than (or of the same quality as) any other operation  $B$ :  $B \preceq A$ .
- For some preference relations, we may have several different optimal combination operations.
- We can then use this non-uniqueness to optimize something else.

## 51. What Is Optimal Pooling (cont-d)

- Example:
  - if there are several different combination operations with the best average-case accuracy,
  - we can select, among them, the one for which the average computation time is the smallest possible.
- If after this, we still get several optimal operations,
  - we can use the remaining non-uniqueness
  - to optimize yet another criterion.
- We do this until we get a *final* criterion, for which there is only one optimal combination operation.

## 52. Scale-Invariance

- Numerical values of a physical quantity depend on the choice of a measuring unit.
- For example, if we replace meters with centimeters, the numerical quantity is multiplied by 100.
- In general:
  - if we replace the original unit with a unit which is  $\lambda$  times smaller,
  - then all numerical values get multiplied by  $\lambda$ .
- It is reasonable to require that the preference relation should not change if we change the measuring unit.
- Let us describe this requirement in precise terms.

## 53. Scale-Invariance (cont-d)

- If, in the original units, we had the operation  $a * b$ , then, in the new units, the operation will be as follows:
  - first, we transform the value  $a$  and  $b$  into the new units, so we get  $a' = \lambda \cdot a$  and  $b' = \lambda \cdot b$ ;
  - then, we combine the new numerical values, getting  $(\lambda \cdot a) * (\lambda \cdot b)$ ;
  - finally, we re-scale the result to the original units, getting  $aR_\lambda(*)b \stackrel{\text{def}}{=} \lambda^{-1} \cdot ((\lambda \cdot a) * (\lambda \cdot b))$ .
- It therefore makes sense to require that if  $* \preceq *'$ , then for every  $\lambda > 0$ , we get  $R_\lambda(*) \preceq R_\lambda(*)'$ .

## 54. Shift-Invariance

- The numerical values also change if we change the starting point for measurements.
- For example, when measuring intensity:
  - we can measure the actual intensity of an image,
  - or we can take into account that there is always some noise  $a_0 > 0$ , and
  - use the noise-only level  $a_0$  as the new starting point.
- In this case, instead of each original value  $a$ , we get a new numerical value  $a' = a - a_0$ .

## 55. Shift-Invariance (cont-d)

- If we apply the combination operation in the new units, then in the old units, we get a slightly different result:
  - first, we transform the value  $a$  and  $b$  into the new units, so we get  $a' = a - a_0$  and  $b' = b - a_0$ ;
  - then, we combine the new numerical values, getting

$$(a - a_0) * (b - a_0);$$

- finally, we re-scale the result to the original units, getting  $aS_{a_0}(*)b \stackrel{\text{def}}{=} (a - a_0) * (b - a_0) + a_0$ .
- It makes sense to require that the preference relation not change if we simply change the starting point.
- So if  $* \preceq *'$ , then for every  $a_0$ , we get  $S_{a_0}(*) \preceq S_{a_0}(*)'$ .

## 56. Weak Version of Shift-Invariance

- Alternatively, we can have a weaker version of this “shift-invariance”.
- Namely, we require that shifts in  $a$  and  $b$  imply a possibly different shift in  $a * b$ , i.e.,
  - if we shift both  $a$  and  $b$  by  $a_0$ ,
  - then the value  $a * b$  is shifted by some value  $f(a_0)$  which is, in general, different from  $a_0$ .
- Now, we are ready to formulate our results.

## 57. Definitions

- By a combination operation, we mean a commutative, associative operation  $a * b$  that:
  - transforms two non-negative real numbers  $a$  and  $b$
  - into a non-negative real number  $a * b$ .
- By an optimality criterion, we need a transitive reflexive relation  $\preceq$  on the set of all combination operations.
- We say that a combination operation  $*_{\text{opt}}$  is optimal w.r.t.  $\preceq$  if  $* \preceq *_{\text{opt}}$  for all combination operations  $*$ .
- We say that  $\preceq$  is final if there exists exactly one  $\preceq$ -optimal combination operation.
- We say that an optimality criterion is scale-invariant if for all  $\lambda > 0$ ,  $* \preceq *'$  implies  $R_\lambda(*) \preceq R_\lambda(*)'$ , where:

$$aR_\lambda(*)b \stackrel{\text{def}}{=} \lambda^{-1} \cdot ((\lambda \cdot a) * (\lambda \cdot b)).$$

## 58. Definitions and First Result

- We say that an optimality criterion is shift-invariant if for all  $a_0$ ,  $* \preceq *'$  implies  $S_{a_0}(*) \preceq S_{a_0}(*)'$ , where:

$$aS_{a_0}(*)b \stackrel{\text{def}}{=} ((a - a_0) * (b - a_0)) + a_0.$$

- We say that  $\preceq$  is weakly shift-invariant if for every  $a_0$ , there exists  $f(a_0)$  s.t.  $* \preceq *'$  implies  $W_{a_0}(*) \preceq W_{a_0}(*)'$ ,

$$\text{where } aW_{a_0}(*)b \stackrel{\text{def}}{=} ((a - a_0) * (b - a_0)) + f(a_0).$$

- **Proposition 1.** For every final, scale- and shift-invariant  $\preceq$ , the optimal combination operation  $*$  is

$$a * b = \min(a, b) \text{ or } a * b = \max(a, b).$$

- This result explains why max-pooling is empirically the best combination operation.
- Note that this result does not contradict uniqueness as we requested.

## 59. Results (cont-d)

- Indeed, there are several different final scale- and shift-invariant optimality criteria.
- For each of these criteria, there is only one optimal combination operation.
- For some of these optimality criteria, the optimal combination operation is  $\min(a, b)$ .
- For other criteria, the optimal combination operation is  $\max(a, b)$ .
- **Proposition 2.** *For every final, scale-invariant and weakly shift-invariant  $\preceq$ , the optimal  $*$  is:*
$$a * b = 0, \quad a * b = \min(a, b), \quad a * b = \max(a, b), \quad \text{or}$$
$$a * b = a + b.$$
- *This result explains why max-pooling and average-pooling are empirically the best combination operations.*

## 60. Why Quantum Computing

- In many practical problems, we need to process large amounts of data in a limited time.
- To be able to do it, we need computations to be as fast as possible.
- Computations are already fast.
- However, there are many important problems for which we still cannot get the results on time.
- For example, we can predict with a reasonable accuracy where the tornado will go in the next 15 minutes.
- However, these computations take days on the fastest existing high performance computer.
- One of the main limitations: the speed of all the processes is limited by the speed of light  $c \approx 3 \cdot 10^5$  km/sec.

## 61. Why Quantum Computing (cont-d)

- For a laptop of size  $\approx 30$  cm, the fastest we can send a signal across the laptop is  $\frac{30 \text{ cm}}{3 \cdot 10^5 \text{ km/sec}} \approx 10^{-9}$  sec.
- During this time, a usual few-Gigaflop laptop performs quite a few operations.
- To further speed up computations, we thus need to further decrease the size of the processors.
- We need to fit Gigabytes of data – i.e., billions of cells – within a small area.
- So, we need to attain a very small cell size.
- At present, a typical cell consists of several dozen molecules.
- As we decrease the size further, we get to a few-molecule size.

## 62. Why Quantum Computing (cont-d)

- At this size, physics is different: quantum effects become dominant.
- At first, quantum effects were mainly viewed as a nuisance.
- For example, one of the features of quantum world is that its results are usually probabilistic.
- So, if we simply decrease the cell size but use the same computer engineering techniques, then:
  - instead of getting the desired results all the time,
  - we will start getting other results with some probability.
- This probability of undesired results increases as we decrease the size of the computing cells.

## 63. Why Quantum Computing (cont-d)

- However, researchers found out that:
  - by appropriately modifying the corresponding algorithms,
  - we can avoid the probability-related problem and, even better, make computations faster.
- The resulting algorithms are known as algorithms of *quantum computing*.

## 64. Lemon into Lemonade

- In non-quantum computing, finding an element in an unsorted database with  $n$  entries may require time  $n$ .
- Indeed, we may need to look at each record.
- In quantum computing, it is possible to find this element in much smaller time  $\sqrt{n}$ .

## 65. Quantum Computing Will Enable Us to Decode All Traditionally Encoded Messages

- One of the spectacular algorithms of quantum computing is Shor's algorithm for fast factorization.
- Most encryption schemes – the backbone of online commerce – are based on the RSA algorithm.
- This algorithm is based on the difficulty of factorizing large integers.
- To form an at-present-unbreakable code, the user selects two large prime numbers  $P_1$  and  $P_2$ .
- These numbers form his private code.
- He then transmits to everyone their product  $n = P_1 \cdot P_2$  that everyone can use to encrypt their messages.
- At present, the only way to decode this message is to know the values  $P_i$ .

## 67. Quantum Cryptography: an Unbreakable Alternative to the Current Cryptographic Schemes

- That RSA-based cryptographic schemes can be broken by quantum computing.
- However, this does not mean that there will be no secrets.
- Researchers have invented a quantum-based encryption scheme that cannot be thus broken.
- This scheme, by the way, is already used for secret communications.

## 69. Quantum Physics: Possible States

- One of the main ideas behind quantum physics is that in the quantum world,
  - in addition to the regular states,
  - we can also have linear combinations of these states, with complex coefficients.
- Such combinations are known as *superpositions*.
- A single 1-bit memory cell in the classical physics can only have states 0 and 1.
- In quantum physics, these states are denoted by  $|0\rangle$  and  $|1\rangle$ .
- We can also have superpositions  $c_0 \cdot |0\rangle + c_1 \cdot |1\rangle$ , where  $c_0$  and  $c_1$  are complex numbers.

## 70. Measurements in Quantum Physics

- What will happen if we try to measure the bit in the superposition state  $c_0 \cdot |0\rangle + c_1 \cdot |1\rangle$ ?
- According to quantum physics, as a result of this measurement, we get:
  - 0 with probability  $|c_0|^2$  and
  - 1 with probability  $|c_1|^2$ .
- After the measurement, the state also changes:
  - if the measurement result is 0, the state will turn into  $|0\rangle$ , and
  - if the measurement result is 1, the state will turn into  $|1\rangle$ .

## 71. Measurements in Quantum Physics (cont-d)

- Since we can get either 0 or 1, the corresponding probabilities should add up to 1; so:
  - for the expression  $c_0 \cdot |0\rangle + c_1 \cdot |1\rangle$  to represent a physically meaningful state,
  - the coefficients  $c_0$  and  $c_1$  must satisfy the condition

$$|c_0|^2 + |c_1|^2 = 1.$$

## 72. Operations on Quantum States

- We can perform *unitary* operations, i.e., linear transformations that preserve the property

$$|c_0|^2 + |c_1|^2 = 1.$$

- A simple example of a unary transformation is *Walsh-Hadamard (WH)* transformation:

$$|0\rangle \rightarrow |0'\rangle \stackrel{\text{def}}{=} \frac{1}{\sqrt{2}} \cdot |0\rangle + \frac{1}{\sqrt{2}} \cdot |1\rangle;$$

$$|1\rangle \rightarrow |1'\rangle \stackrel{\text{def}}{=} \frac{1}{\sqrt{2}} \cdot |0\rangle - \frac{1}{\sqrt{2}} \cdot |1\rangle.$$

- What is the geometric meaning of this transformation?

## 73. Operations on Quantum States (cont-d)

- By linearity:  $c'_0 \cdot |0'\rangle + c'_1 \cdot |1'\rangle =$

$$c'_0 \cdot \left( \frac{1}{\sqrt{2}} \cdot |0\rangle + \frac{1}{\sqrt{2}} \cdot |1\rangle \right) + c'_1 \cdot \left( \frac{1}{\sqrt{2}} \cdot |0\rangle - \frac{1}{\sqrt{2}} \cdot |1\rangle \right) = \\ \left( \frac{1}{\sqrt{2}} \cdot c'_0 + \frac{1}{\sqrt{2}} \cdot c'_1 \right) \cdot |0\rangle + \left( \frac{1}{\sqrt{2}} \cdot c'_0 - \frac{1}{\sqrt{2}} \cdot c'_1 \right) \cdot |1\rangle.$$

- Thus,  $c'_0 \cdot |0'\rangle + c'_1 \cdot |1'\rangle = c_0 \cdot |0\rangle + c_1 \cdot |1\rangle$ , where

$$c_0 = \frac{1}{\sqrt{2}} \cdot c'_0 + \frac{1}{\sqrt{2}} \cdot c'_1 \text{ and } c_1 = \frac{1}{\sqrt{2}} \cdot c'_0 - \frac{1}{\sqrt{2}} \cdot c'_1.$$

- Let us represent each of the two pairs  $(c_0, c_1)$  and  $(c'_0, c'_1)$  as a point in the 2-D plane  $(x, y)$ .
- Then the above transformation resembles the formulas for a clockwise rotation by an angle  $\theta$ :

$$x' = \cos(\theta) \cdot x + \sin(\theta) \cdot y; \\ y' = -\sin(\theta) \cdot x + \cos(\theta) \cdot y.$$

## 74. Operations on Quantum States (cont-d)

- Specifically, for  $\theta = 45^\circ$ , we have  $\cos(\theta) = \sin(\theta) = \frac{1}{\sqrt{2}}$  and thus, the rotation takes the form

$$x' = \frac{1}{\sqrt{2}} \cdot x + \frac{1}{\sqrt{2}} \cdot y; \quad y' = -\frac{1}{\sqrt{2}} \cdot x + \frac{1}{\sqrt{2}} \cdot y.$$

- In these terms, can see that the WH transformation from  $(c'_0, c'_1)$  and  $(c_0, c_1)$  is:
  - a rotation by 45 degrees
  - followed by a reflection with respect to the  $x$ -axis:  
 $(c_0, c_1) \rightarrow (c_0, -c_1)$ .
- One can check that if we apply WH transformation twice, then we get the same state as before.

## 76. Measurements of Quantum 1-Bit Systems

- According to quantum measurement:
  - if we measure the bit 0 or 1 in each of the states  $|0'\rangle$  or  $|1'\rangle$ ,
  - then we will get 0 or 1 with equal probability  $1/2$ .
- So, if we measure 0 or 1, then:
  - if we are in the state  $|0\rangle$ , then the state does not change and we get 0 with probability 1;
  - if we are in the state  $|1\rangle$ , then the state does not change and we get 1 with probability 1;
  - if we are in one of the states  $|0'\rangle$  or  $|1'\rangle$ , then:
    - \* with probability  $1/2$ , we get the measurement result 0 and the state changes into  $|0\rangle$ ; and
    - \* with probability  $1/2$ , we get the measurement result 1 and the state changes into  $|1\rangle$ .

## 78. Main Idea of Quantum Cryptography

- The sender – who, in cryptography, is usually called Alice – sends each bit
  - either as  $|0\rangle$  or  $|1\rangle$  (this orientation is usually denoted by  $+$ )
  - or as  $|0'\rangle$  or  $|1'\rangle$  (this orientation is usually denoted by  $\times$ ).
- The receiver – who, in cryptography, is usually called Bob – tries to extract the information from the signal.
- Extracting numerical information from a physical object is nothing else but measurement.
- Thus, to extract the information from Alice's signal, Bob needs to perform some measurement.
- Since Alice uses one of the two orientations  $+$  or  $\times$ , it is reasonable for Bob to also use one of these orientations.

## 79. Sender and Receiver Must Use the Same Orientation

- If for some bit:
  - Alice and Bob use the same orientation,
  - then Bob will get the exact same signal that Alice has sent.
- The situation is completely different if Alice and Bob use different orientations.
- For example, assume that:
  - Alice sends a 0 bit in the  $\times$  orientation, i.e., sends the state  $|0'\rangle$ , and
  - Bob uses the  $+$  orientation to measure the signal.

## 80. We Need Same Orientation (cont-d)

- For the state  $|0'\rangle = \frac{1}{\sqrt{2}} \cdot |0\rangle + \frac{1}{\sqrt{2}} \cdot |1\rangle$ :
  - with probability  $\left|\frac{1}{\sqrt{2}}\right|^2 = \frac{1}{2}$ , Bob will measure 0, and
  - with probability  $\left|\frac{1}{\sqrt{2}}\right|^2 = \frac{1}{2}$ , Bob will measure 1.
- The same results, with the same probabilities, will happen if Alice sends a 1 bit in the  $\times$  orientation, i.e.,  $|1'\rangle$ .
- Thus, by observing the measurement result, Bob will not be able to tell whether Alice send 0 or 1.
- The information will be lost.
- Similarly, the information will be lost if Alice uses a  $+$  orientation and Bob uses a  $\times$  orientation.

## 81. What If We Have an Eavesdropper?

- What if an eavesdropper – usually called Eve – gains access to the same communication channel?
- In non-quantum eavesdropping, Eve can measure each bit that Alice sends and thus, get the whole message.
- In non-quantum physics, measurement does not change the signal.
- Thus, Bob gets the same signal that Alice has sent.
- Neither Alice nor Bob will know that somebody eavesdropped on their communication.
- In quantum physics, the situation is different.
- One of the main features of quantum physics is that measurement, in general, changes the signal.
- Eve does not know in which of the two orientations each bit is sent.

## 82. What If We Have an Eavesdropper (cont-d)

- So, she can select the wrong orientation for her measurement.
- As a result, e.g.,
  - if Alice and Bob agreed to use the  $\times$  orientation for transmitting a certain bit,
  - but Eve selects a  $+$  orientation,
  - then Eve's measurement will change Alice's signal
  - and Bob will only get the distorted message.
- For example, if Alice sent  $|0'\rangle$ , then:
  - after Eve's measurement,
  - the signal will become either  $|0\rangle$  or  $|1\rangle$ , with probability  $1/2$  of each of these options.

## 84. Quantum Cryptography Helps to Detect an Eavesdropper

- If there is an eavesdropper, then:
  - with certain probability,
  - the signal received by Bob will be different from what Alice sent.
- Thus, by comparing what Alice sent with what Bob received, we can see that something was interfering.
- Thus, we will be able to detect the presence of the eavesdropper.
- Let us describe how this idea is implemented in the current quantum cryptography algorithm.

## 85. Sending a Preliminary Message

- Before Alice sends the actual message, she needs to check that the communication channel is secure.
- For this purpose, Alice uses a random number generator to select  $n$  random bits  $b_1, \dots, b_n$ .
- Each of them is equal to 0 or 1 with probability  $1/2$ .
- These bits will be sent to Bob.
- Alice also selects  $n$  more random bits  $r_1, \dots, r_n$ .
- Based on these bits, Alice sends the bits  $b_i$  as follows:
  - if  $r_i = 0$ , then the bit  $b_i$  is sent in  $+$  orientation, i.e., Alice sends  $|0\rangle$  if  $b_i = 0$  and  $|1\rangle$  if  $b_i = 1$ ;
  - if  $r_i = 1$ , then the bit  $b_i$  is sent in  $\times$  orientation, i.e., Alice sends  $|0'\rangle$  if  $b_i = 0$  and  $|1'\rangle$  if  $b_i = 1$ .

## 86. Receiving the Preliminary Message

- Independently, Bob selects  $n$  random bits  $s_1, \dots, s_n$ .
- They determine how he measures the signal that he receives from Alice:
  - if  $s_i = 0$ , then Bob measures whether the  $i$ -th received signal is  $|0\rangle$  or  $|1\rangle$ ;
  - if  $s_i = 1$ , then Bob measures whether the  $i$ -th received signal is  $|0'\rangle$  or  $|1'\rangle$ .

## 87. Checking for Eavesdroppers

- After this, for  $k$  out of  $n$  bits, Alice openly sends to Bob her bits  $b_i$  and her orientations  $r_i$ .
- Bob sends to Alice his orientations  $s_i$  and the signals  $b'_i$  that he measured.
- In half of the cases, the orientations  $r_i$  and  $s_i$  should coincide.
- In which case, if there is no eavesdropper,
  - the signal  $b'_i$  measured by Bob
  - should coincide with the signal  $b_i$  that Alice sent.
- So, if  $b'_i \neq b_i$  for some  $i$ , this means that there is an eavesdropper.
- If there is an eavesdropper, then with probability  $1/2$ , Eve will select a different orientation.

## 88. Checking for Eavesdroppers (cont-d)

- In half of such cases, the eavesdropping will change the original signal.
- So, for each bit, the probability that we will have  $b'_i \neq b_i$  is equal to  $1/4$ .
- Thus, the probability that the eavesdropper will not be detected by this bit is  $1 - 1/4 = 3/4$ .
- The probability that Eve will not be detected in all  $k/2$  cases is the product  $(3/4)^{k/2}$ .
- For a sufficiently large  $k$ , this probability of not-detecting-eavesdropping is very small.
- Thus, if  $b'_i = b_i$  for all  $k$  bits  $i$ , this means that with high confidence, there is no eavesdropping.
- So, the communication channel between Alice and Bob is secure.

## 89. Preparing to Send a Message

- Now, for each of the remaining  $(n - k)$  bits, Alice and Bob openly exchange orientations  $r_i$  and  $s_i$ .
- For half of these bits, these orientations must coincide.
- For these bits, since there is no eavesdropping, Alice and Bob know that:
  - the signal  $b'_i$  measured by Bob
  - is the same as the signal  $b_i$  sent to Alice.
- So, there are  $B \stackrel{\text{def}}{=} (n - k)/2$  bits  $b_i = b'_i$  that they both know but no one else knows.

## 90. Sending and Receiving the Actual Message

- Now, Alice takes the  $B$ -bit message  $m_1, \dots, m_B$  that she wants to send.
- She forms the encoded message  $m'_i \stackrel{\text{def}}{=} m_i \oplus b_i$ , where  $\oplus$  means addition modulo 2 (same as exclusive or).
- Alice openly sends the encoded message  $m'_i$ .
- Upon receiving the message  $m'_i$ , Bob reconstructs the original message as  $m_i = m'_i \oplus b_i$ .

## 91. A General Family of Quantum Cryptography Algorithms: Description

- In the current quantum cryptography algorithm, Alice selects  $+$  and  $\times$  with probability 0.5.
- Similarly, Bob selects one of the two possible orientations  $+$  and  $\times$  with probability 0.5.
- It is therefore reasonable to consider a more general scheme, in which:
  - Alice selects the orientation  $+$  with some probability  $a_+$  (which is not necessarily equal to 0.5), and
  - Bob select the orientation  $+$  with some probability  $b_+$  (which is not necessarily equal to 0.5).
- Which  $a_+$  and  $b_+$  should they choose to make the connection maximally secure?
- I.e., to maximize the probability of detecting the eavesdropper?

## 92. What Do We Want to Maximize?

- We want to maximize the probability of detecting an eavesdropper.
- The eavesdropper also selects one of the two orientations  $+$  or  $\times$ .
- Let  $e_+$  be the probability with which the eavesdropper (Eve) select the orientation  $+$ .
- Then Eve will select  $\times$  with the remaining probability  $e_\times = 1 - e_+$ .
- We know that Alice and Bob can only use bits for which their selected orientations coincide.
- If Eve selects the same orientation, then her observation will also not change this bit.
- Thus, we will not be able to detect the eavesdropping.

### 93. What Do We Want to Maximize (cont-d)

- We can detect the eavesdropping only when  $A$  and  $B$  have the same orientation, but  $E$  has a different one.
- There are two such cases:
  - the first case is when Alice and Bob select  $+$  and Eve selects  $\times$ ;
  - the second case is when Alice and Bob select  $\times$  and Eve selects  $+$ .
- Alice, Bob, and Eve act independently.
- So, the probability of the 1st case is  $p_1 = a_+ \cdot b_+ \cdot e_\times$ , where:
  - $a_+$  is the probability that Alice selects  $+$ ,
  - $b_+$  is the probability that Bob selects  $+$ ,
  - $e_\times$  is the probability that Eve selects  $\times$ .

## 94. What Do We Want to Maximize (cont-d)

- Similarly, the probability  $p_2$  of the 2nd case is  $p_1 = a_{\times} \cdot b_{\times} \cdot e_{+}$
- These two cases are incompatible.
- So the overall probability  $p$  of detecting the eavesdropper is the sum of the above two probabilities:

$$p = a_{+} \cdot b_{+} \cdot e_{\times} + a_{\times} \cdot b_{\times} \cdot e_{+}.$$

- Taking into account that  $a_{\times} = 1 - a_{+}$ ,  $b_{\times} = 1 - b_{+}$ , and  $e_{\times} = 1 - e_{+}$ , we get:

$$p = a_{+} \cdot b_{+} \cdot (1 - e_{+}) + (1 - a_{+}) \cdot (1 - b_{+}) \cdot e_{+}.$$

- This probability depends on Eve's selection  $e_{+}$ .
- We want to maximize the worst-case probability of detection, when Eve uses her best strategy:

$$J = \min_{e_{+} \in [0,1]} \{a_{+} \cdot b_{+} \cdot (1 - e_{+}) + (1 - a_{+}) \cdot (1 - b_{+}) \cdot e_{+}\}.$$

## 95. Analyzing the Optimization Problem

- Once the values  $a_+$  and  $b_+$  are fixed, the expression that Eve wants to minimize is a linear function of  $e_+$ :

$$\begin{aligned} p &= a_+ \cdot b_+ - a_+ \cdot b_+ \cdot e_+ + (1 - a_+) \cdot (1 - b_+) \cdot e_+ = \\ &= a_+ \cdot b_+ + e_+ \cdot ((1 - a_+) \cdot (1 - b_+) - a_+ \cdot b_+). \end{aligned}$$

- We want to minimize this expression over all possible values of  $e_+$  from the interval  $[0, 1]$ .
- A linear function on an interval always attains its min at one of the endpoints.
- Thus, to find the minimum of the above expression over  $e_+$ , it is sufficient:
  - to consider the two endpoints  $e_+ = 0$  and  $e_+ = 1$  of this interval, and
  - take the smallest of the resulting two values.

## 96. Analyzing the Optimization Problem (cont-d)

- For  $e_+ = 0$ , the expression becomes  $a_+ \cdot b_+$ .
- For  $e_+ = 1$ , the expression becomes  $(1 - a_+) \cdot (1 - b_+)$ .
- Thus, the minimum of the expression can be equivalently described as:

$$J = \min\{a_+ \cdot b_+, (1 - a_+) \cdot (1 - b_+)\}.$$

- We need to find the values  $a_+$  and  $b_+$  for which this quantity attains its largest possible value.
- Let us first, for each  $a_+$ , find the value  $b_+$  for which the  $J$  attains its maximum possible value.
- In the formula for  $J$ ,  $a_+ \cdot b_+$ , is increasing from 0 to  $a_+$  as  $b_+$  goes from 0 to 1.
- The second expression  $(1 - a_+) \cdot (1 - b_+)$  decreases from  $1 - a_+$  to 0 as  $b_+$  goes from 0 to 1.

## 97. Analyzing the Optimization Problem (cont-d)

- Thus, for small  $b_+$ , the first of the two expressions is smaller.
- So, for these  $b_+$ ,  $J = a_+ \cdot b_+$  and is, thus, increasing with  $b_+$ ;
- For larger  $b_+$ , the second of the two expressions is smaller.
- Thus for these  $b_+$ ,  $J = (1 - a_+) \cdot (1 - b_+)$  and is, so, decreasing with  $b_+$ .
- So  $J$  first increases and then decreases.
- Thus, its maximum is attained at a point when  $J$  switches from increasing to decreasing, i.e., where:

$$a_+ \cdot b_+ = (1 - b_+) \cdot (1 - a_+), \text{ i.e.,}$$

$$a_+ \cdot b_+ = 1 - a_+ - b_+ + a_+ \cdot b_+, \text{ so } b_+ = 1 - a_+.$$

## 98. Analyzing the Optimization Problem (cont-d)

- Substituting  $b_+ = 1 - a_+$  into the formula for  $J$ , we get
$$J = \min\{a_+ \cdot (1 - a_+), (1 - a_+) \cdot a_+\} = a_+ \cdot (1 - a_+).$$
- We want to find the value  $a_+$  that maximizes this expression: it is  $a_+ = 0.5$ .
- Since  $b_+ = 1 - a_+$ , we get  $b_+ = 1 - 0.5 = 0.5$ .
- Thus, the current quantum cryptography algorithm is indeed optimal.
- Similar arguments show:
  - that the best is to use 45 degrees rotation, and
  - that the best is to have 0s and 1s in  $b_i$  with probability 0.5.

## 99. Another Issue: Need for Parallel Quantum Computing

- While quantum computing is fast, its speeds are also limited.
- To further speed up computations, a natural idea is to have several quantum computers working in parallel.
- Then each of them solves a part of the problem.
- This idea is similar to how we humans solve complex problems:
  - if a task is too difficult for one person to solve – be it building a big house or proving a theorem,
  - several people team up and together solve the task.

## 100. Need for Teleportation

- To successfully collaborate, quantum computers need to exchange intermediate states of their computations.
- Here lies a problem: for complex problems, we would like to use computers in different geographic areas.
- However, a quantum state gets changed when it is sent far away.
- Researchers have come up with a way to avoid this sending, called *teleportation*.
- There exists a scheme for teleportation.

## 101. Problem

- It is not clear how good is the current teleportation scheme.
- Maybe there are other schemes which are faster (or better in some other sense)?
- In this tutorial, we show that the existing teleportation scheme is, in some reasonable sense, unique.
- In this sense, this sense is the best.
- To explain this result, we start by a brief reminder of the basics of quantum physics.

## 102. Basic States in Quantum Physics

- In quantum physics:
  - in addition to the usual (non-quantum) states  $s_1, s_2, \dots$ ,
  - we also have *superpositions* of these states, i.e., states of the type  $\alpha_1 \cdot s_1 + \alpha_2 \cdot s_2 + \dots$
- Here  $\alpha_1, \alpha_2, \dots$  are complex numbers (called *amplitudes*) for which  $|\alpha_1|^2 + |\alpha_2|^2 + \dots = 1$ .
- For example, a computer is formed from devices representing *binary digits* (*bits*, for short).
- These devices can be in two possible states: 0 and 1.
- In quantum physics, we also have superpositions  $\alpha_0 \cdot |0\rangle + \alpha_1 \cdot |1\rangle$ , where  $|\alpha_0|^2 + |\alpha_1|^2 = 1$ .
- The corresponding quantum system is known as a *quantum bit*, or *qubit*, for short.

## 103. Composite States in Quantum Physics

- There is a straightforward way to describe a composite system consisting of two independent subsystems.
- Due to independence, to describe the set of the system as a whole, it is sufficient to describe:
  - the state  $s$  of the first subsystem and
  - the state  $s'$  of the second subsystem.
- Thus, a state of the system as a whole is an ordered pair  $\langle s, s' \rangle$  of the two states; let us denote:
  - possible states of the 1st subsystem by  $s_1, s_2, \dots$ ;
  - possible states of the 2nd subsystem by  $s'_1, s'_2, \dots$
- The subsystems are independent.
- So, the possible states of the 1st subsystem do not depend on the state of the 2nd.

## 104. Composite States (cont-d)

- Thus, the set of all states of the system as a whole is the set of all possible pairs  $\langle s_i, s'_j \rangle$ .
- The set of all such pairs is known as the *Cartesian product*; it is denoted by  $\{s_1, s_2, \dots\} \times \{s'_1, s'_2, \dots\}$ .
- These notations are usually simplified: e.g.,  $\langle 0, 1 \rangle$  is denoted simply as 01.
- In quantum physics, we can also have superpositions of such states, i.e., the states of the type
$$\alpha_{11} \cdot \langle s_1, s'_1 \rangle + \alpha_{12} \cdot \langle s_1, s'_2 \rangle + \dots + \alpha_{21} \cdot \langle s_2, s'_1 \rangle + \alpha_{22} \cdot \langle s_2, s'_2 \rangle + \dots$$
- Here,  $|\alpha_{11}|^2 + |\alpha_{12}|^2 + \dots + |\alpha_{21}|^2 + |\alpha_{22}|^2 + \dots = 1$ .
- To describe such a state, we need to know all the values  $\alpha_{ij}$ .
- These values form a matrix – i.e., in mathematical terms, a *tensor*.

## 105. Composite States (cont-d)

- Because of this fact, the set of all such states is known as the *tensor product*  $S \otimes S'$ , where:
  - $S$  is the set of all possible quantum states of the first subsystem and
  - $S'$  is the set of all possible quantum states of the second subsystem.
- So, the pair  $\langle s, s' \rangle$  is denoted by  $s \otimes s'$  and called a *tensor product* of the states  $s$  and  $s'$ :
  - if the first subsystem is in the state  $s_i$  and the second subsystem is in the state  $s'_j$ ,
  - then the state of the system is  $\langle s_i, s'_j \rangle = s_i \otimes s'_j$ .
- If  $s = \alpha_1 \cdot s_1 + \alpha_2 \cdot s_2 + \dots$  and  $s' = \alpha'_1 \cdot s'_1 + \alpha'_2 \cdot s'_2 + \dots$ , then  $s \otimes s' = \sum_{i,j} \alpha_i \cdot \alpha'_j \cdot s_i \otimes s'_j$ .

## 106. Transformations in Quantum Physics

- Physically possible transformation are the mappings from state to state that satisfy the following properties:
  - superpositions get transformed into similar superpositions:

$$T(\alpha_1 \cdot s_1 + \alpha_2 \cdots s_2 + \dots) = \alpha_1 \cdot T(s_1) + \alpha_2 \cdot T(s_2) + \dots,$$

- $\sum |\alpha_i|^2 = 1$  is preserved: if  $\sum |\alpha_i|^2 = 1$ , then, for  $T(\sum \alpha_i \cdot s_i) = \sum \beta_i \cdot s_i$ , we have  $\sum |\beta_i|^2 = 1$ .

- Because of the first property, transformations are linear:  $\sum \alpha_i \cdot s_i \rightarrow \sum \beta_i \cdot s_i$ , with  $\beta_i = \sum_j t_{ij} \cdot \alpha_j$ .
- Because of the second property, the matrix  $T = (t_{ij})$  is *unitary*, i.e.,  $TT^\dagger = \mathbf{1}$ , where  $\mathbf{1}$  is a unit matrix.
- Here,  $T^\dagger \stackrel{\text{def}}{=} (t_{ji}^*)$ , with  $z^*$  denoting the complex conjugate number  $(a + b \cdot i)^* \stackrel{\text{def}}{=} a - b \cdot i$ .

## 107. Measurement Process in Quantum Physics

- For binary states  $\alpha_0 \cdot |0\rangle + \alpha_1 \cdot |1\rangle$ , if we want to measure whether the state is 0 or 1, then:
  - with probability  $|\alpha_0|^2$ , we get the result 0 – and the state turns into  $|0\rangle$ ; and
  - with probability  $|\alpha_1|^2$ , we get the result 1 – and the state turns into  $|1\rangle$ .
- Since the result is either 0 or 1, the probabilities should add up to 1.
- This explains why physically possible states should satisfy the condition  $|\alpha_0|^2 + |\alpha_1|^2 = 1$ .
- In general, in a quantum state  $\sum \alpha_i \cdot s_i$ , we get  $s_i$  with probability  $|\alpha_i|^2$ .
- Once the measurement process detects the state  $s_i$ , the actual state turns into  $s_i$ .

## 108. Measurement Process (cont-d)

- Instead of the classical states  $s_i$ , we can use any orthonormal sequence of states  $s'_i = \sum_j t_{ij} \cdot s_j$ :

– for each  $i$ , we have  $\|s'_i\|^2 = 1$ , where  $\|s'_i\|^2 \stackrel{\text{def}}{=} \sum_j |t_{ij}|^2$

(*normal*), and

– for each  $i$  and  $i'$ , we have  $s'_i \perp s'_{i'}$ , i.e.,  $\langle s'_i | s'_{i'} \rangle = 0$ ,  
where  $\langle s'_i | s'_{i'} \rangle \stackrel{\text{def}}{=} \sum_j t_{ij} \cdot t_{i'j}^*$  (*orthogonal*).

- In a state  $\sum \alpha'_i \cdot s'_i$ , with probability  $|\alpha'_i|^2$ , the measurement result is  $s'_i$  and the state turns into  $s'_i$ .
- In general, instead of orthogonal vectors, we can have a sequence of orthogonal linear spaces  $L_1, L_2, \dots$
- Here  $L_i \perp L_j$  means that  $s_i \in L_i$  and  $s_j \in L_j$  implies

$$s_i \perp s_j.$$

## 110. Need for Communication

- At one location, we have a particle in a certain state.
- We want to send this state to some other location.
- Usually, the sender is denoted by  $A$  and the receiver by  $B$ .
- In communications, it is common to call the sender Alice, and to call the receiver Bob:
  - states corresponding to Alice are usually described by using a subscript  $A$ , and
  - states corresponding to Bob are usually described by using a subscript  $B$ .

## 111. Communication Is Straightforward in Classical Physics

- In classical (pre-quantum) physics, the communication problem has a straightforward solution.
- If we want to communicate a state:
  - we measure all possible characteristics of this state,
  - send these values to Bob, and
  - let Bob reproduce the object with these characteristics.
- This is how, e.g., 3D printing works.
- This solution is based on the fact that:
  - in classical (non-quantum) physics
  - we can, in principle, measure all characteristic of a system without changing it.

## 112. Communication Is a Challenge in Quantum Physics

- The problem is that in quantum physics, such a straightforward approach is not possible.
- In quantum physics, every measurement changes the state.
- Moreover, each measurement irreversibly deletes some information about the state.
- For example, if we start with a state  $\alpha_0 \cdot |0\rangle + \alpha_1 \cdot |1\rangle$ , all we get after the measurement is either 0 or 1.
- There is no way to reconstruct the values  $\alpha_0$  and  $\alpha_1$  that characterize the original state.
- Since we cannot use a direct approach for communicating a state, we need to use an indirect approach.
- This approach is known as *teleportation*.

## 113. What We Consider in This Tutorial

- We consider the quantum analogue of the simplest possible non-quantum state.
- The simplest case when communication is needed is when the system can be in two different states.
- In the computer, such situation can be naturally described if we associate these states with 0 and 1.
- Alice has a state  $\alpha_0 \cdot |0\rangle + \alpha_1 \cdot |1\rangle$  that she wants to communicate to Bob.
- The above state is not exclusively Alice's or Bob's.
- So, to describe this state, we will use the next letter  $C$ .
- In these terms, Alice has a state  $\alpha_0 \cdot |0\rangle_C + \alpha_1 \cdot |1\rangle_C$ .
- She wants to communicate this state to Bob.

## 114. Preparing for Teleportation: an Entangled State

- To make teleportation possible, Alice and Bob prepare a special *entangled* state:

$$\frac{1}{\sqrt{2}} \cdot |0_A 1_B\rangle + \frac{1}{\sqrt{2}} \cdot |1_A 0_B\rangle.$$

- This state is a superposition of two classical states:
  - the state  $0_A 1_B$  in which A is in state 0 and B is in state 1, and
  - the state  $1_A 0_B$  in which A is in state 1 and B is in state 0.
- At first, the state  $C$  is independent of  $A$  and  $B$ .
- So, the joint state is a tensor product of the  $AB$ -state and the  $C$ -state:

$$\frac{\alpha_0}{\sqrt{2}} \cdot |0_A 1_B 0_C\rangle + \frac{\alpha_1}{\sqrt{2}} \cdot |0_A 1_B 1_C\rangle + \frac{\alpha_0}{\sqrt{2}} \cdot |1_A 0_B 0_C\rangle + \frac{\alpha_1}{\sqrt{2}} \cdot |1_A 0_B 1_C\rangle.$$

## 115. First Stage: Measurement

- First, Alice performs a measurement procedure on the parts  $A$  and  $C$  which are available to her.
- We perform the measurement w.r.t.  $L_i = L_B \otimes t_i$ .
- Here,  $L_B$  is the set of all possible linear combinations of  $|0\rangle_B$  and  $|1\rangle_B$ .
- The states  $t_i$  are as follows:

$$t_1 = \frac{1}{\sqrt{2}} \cdot |0_A 0_C\rangle + \frac{1}{\sqrt{2}} \cdot |1_A 1_C\rangle;$$

$$t_2 = \frac{1}{\sqrt{2}} \cdot |0_A 0_C\rangle - \frac{1}{\sqrt{2}} \cdot |1_A 1_C\rangle;$$

$$t_3 = \frac{1}{\sqrt{2}} \cdot |0_A 1_C\rangle + \frac{1}{\sqrt{2}} \cdot |1_A 0_C\rangle;$$

$$t_4 = \frac{1}{\sqrt{2}} \cdot |0_A 1_C\rangle - \frac{1}{\sqrt{2}} \cdot |1_A 0_C\rangle.$$

## 116. First Stage: Measurement (cont-d)

- One can easily check that the states  $t_i$  are orthonormal, hence the spaces  $L_i$  are orthogonal.
- Let's represent the state in as  $s = \sum s_i$ , with  $s_i \in L_i$ :

$$s_1 = \left( \frac{\alpha_0}{2} \cdot |1_B\rangle + \frac{\alpha_1}{2} |0_B\rangle \right) \otimes t_1,$$

$$s_2 = \left( \frac{\alpha_0}{2} \cdot |1_B\rangle - \frac{\alpha_1}{2} \cdot |0_B\rangle \right) \otimes t_2,$$

$$s_3 = \left( \frac{\alpha_1}{2} \cdot |1_B\rangle + \frac{\alpha_0}{2} \cdot |0_B\rangle \right) \otimes t_3,$$

$$s_4 = \left( \frac{\alpha_1}{2} \cdot |1_B\rangle - \frac{\alpha_0}{2} \cdot |0_B\rangle \right) \otimes t_4.$$

- Here, for each  $i$ , we have  $\|s_i\| = \frac{1}{2}$ .

## 117. First Stage: Measurement (cont-d)

- So, with equal probability of  $\frac{1}{4}$ , we get one of the following four states – and Alice knows which one it is:

$$(\alpha_0 \cdot |1_B\rangle + \alpha_1 \cdot |0_B\rangle) \otimes t_1;$$

$$(\alpha_0 \cdot |1_B\rangle - \alpha_1 \cdot |0_B\rangle) \otimes t_2;$$

$$(\alpha_1 \cdot |1_B\rangle + \alpha_0 \cdot |0_B\rangle) \otimes t_3;$$

$$(\alpha_1 \cdot |1_B\rangle - \alpha_0 \cdot |0_B\rangle) \otimes t_4.$$

## 118. Two Final Stages

- Alice sends to Bob the measurement result.
- So, Bob knows in which the four states the system is.
- Bob performs a transformation of his state  $B$ .
- In the first case, he uses a unitary transformation that swaps  $|0\rangle_B$  and  $|1\rangle_B$ :  $t_{01} = t_{10} = 1$  and  $t_{00} = t_{11} = 0$ .
- In the second case, he uses a unitary transformation for which  $t_{01} = 1$ ,  $t_{10} = -1$  and  $t_{00} = t_{11} = 0$ .
- In the third case, he already has the desired state.
- In the fourth case, he uses a unitary transformation for which  $t_{00} = -1$ ,  $t_{11} = 1$ , and  $t_{01} = t_{10} = 0$ .
- As a result, in all four cases, he gets the original state  $\alpha_0 \cdot |0\rangle_B + \alpha_1 \cdot |1\rangle_B$ .

## 119. Formulation of the Problem

- Teleportation is possible because we have prepared an *entangled* state.
- This is a state  $s_{AB}$  in which the states of Alice and Bob are not independent.
- However, the above is not the only possible entangled state.
- Let us consider, instead, a general joint state of two qubits:

$$a_{00} \cdot |0_A 0_B\rangle + a_{01} \cdot |0_A 1_B\rangle + a_{10} \cdot |1_A 0_B\rangle + a_{11} \cdot |1_A 1_B\rangle.$$

- What will happen if we use this more general entangled state?

## 120. Analysis of the Problem

- For the general state, the joint state of all three subsystems has the form

$$\begin{aligned} & \alpha_0 \cdot a_{00} \cdot |0_A 0_B 0_C\rangle + \alpha_1 \cdot a_{00} \cdot |0_A 0_B 1_C\rangle + \\ & \alpha_0 \cdot a_{01} \cdot |0_A 1_B 0_C\rangle + \alpha_1 \cdot a_{01} \cdot |0_A 1_B 1_C\rangle + \\ & \alpha_0 \cdot a_{10} \cdot |1_A 0_B 0_C\rangle + \alpha_1 \cdot a_{10} \cdot |1_A 0_B 1_C\rangle + \\ & \alpha_0 \cdot a_{11} \cdot |1_A 1_B 0_C\rangle + \alpha_1 \cdot a_{11} \cdot |1_A 1_B 1_C\rangle. \end{aligned}$$

- Substituting expressions for  $s_i$ , we get  $s = S_1 \otimes t_1 + S_2 \otimes t_2 + \dots$ , where:

$$S_1 = \left( \frac{\alpha_0 \cdot a_{00}}{\sqrt{2}} + \frac{\alpha_1 \cdot a_{10}}{\sqrt{2}} \right) \cdot |0\rangle_B + \left( \frac{\alpha_0 \cdot a_{01}}{\sqrt{2}} + \frac{\alpha_1 \cdot a_{11}}{\sqrt{2}} \right) \cdot |1\rangle_B.$$

- $S_2, \dots$  are described by similar expressions.
- This means that after the measurement, Bob will have the normalized state  $S_1 / \|S_1\|$ .

## 121. Analysis of the Problem (cont-d)

- To perform teleportation, we need to transform this state into the original state  $\alpha_0 \cdot |0\rangle_B + \alpha_1 \cdot |1\rangle_B$ .
- Thus, the transformation from the resulting state  $S_1/\|S_1\|$  to the original state must be unitary.
- It is known that the inverse transformation to a unitary one is also unitary.
- In general, a unitary transformation transforms orthonormal states into orthonormal ones.

## 122. Analysis of the Problem (cont-d)

- So, the inverse transformation:
  - maps the state  $|0\rangle_B$  (corresponding to  $\alpha_0 = 1$  and  $\alpha_1 = 0$ ) into a new state

$$|1'\rangle_B \stackrel{\text{def}}{=} \text{const} \cdot (a_{00} \cdot |0\rangle_B + a_{01} \cdot |1\rangle_B),$$

- maps the state  $|1\rangle_B$  (corresponding to  $\alpha_0 = 0$  and  $\alpha_1 = 1$ ) into a new state

$$|0'\rangle_B \stackrel{\text{def}}{=} \text{const} \cdot (a_{10} \cdot |0\rangle_B + a_{11} \cdot |1\rangle_B).$$

- It should transform two original orthonormal vectors  $|0\rangle_B, |1\rangle_B$  into two new orthonormal ones  $|0'\rangle_B, |1'\rangle_B$ .
- In terms of these new states, the entangled state is

$$\text{const} \cdot (|0\rangle_A \otimes |1'\rangle_B + |1\rangle_A \otimes |0'\rangle_B).$$

- The sum of the squares of absolute values of all the coefficients should add up to 1.

## 124. Quantum Part: Conclusion

- From the technical viewpoint:
  - the only entangled state that leads to a successful teleportation
  - is the state corresponding to the standard quantum teleportation algorithm,
  - for some orthonormal states  $|0'\rangle_B$  and  $|1'\rangle_B$ .
- Thus, we have shown that, indeed, the existing quantum teleportation algorithm is unique.
- So we should not waste our time and effort looking for more efficient alternative teleportation algorithms.

## 125. Why Fractional Linear

- Every transformation is a composition of infinitesimal ones  $x \rightarrow x + \varepsilon \cdot f(x)$ , for infinitely small  $\varepsilon$ .
- So, it's enough to consider infinitesimal transformations.
- The class of the corresponding functions  $f(x)$  is known as a *Lie algebra*  $A$  of the corresponding transformation group.
- Infinitesimal linear transformations correspond to  $f(x) = a + b \cdot x$ , so all linear functions are in  $A$ .
- In particular,  $1 \in A$  and  $x \in A$ .
- For any  $\lambda$ , the product  $\varepsilon \cdot \lambda$  is also infinitesimal, so we get  $x \rightarrow x + (\varepsilon \cdot \lambda) \cdot f(x) = x \rightarrow x + \varepsilon \cdot (\lambda \cdot f(x))$ .
- So, if  $f(x) \in A$ , then  $\lambda \cdot f(x) \in A$ .

## 126. Why Fractional Linear (cont-d)

- If we first apply  $f(x)$ , then  $g(x)$ , we get

$$x \rightarrow (x + \varepsilon \cdot f(x)) + \varepsilon \cdot g(x + \varepsilon \cdot f(x)) = x + \varepsilon \cdot (f(x) + g(x)) + o(\varepsilon).$$

- Thus, if  $f(x) \in A$  and  $g(x) \in A$ , then  $f(x) + g(x) \in A$ .
- So,  $A$  is a linear space.
- In general, for the composition, we get

$$x \rightarrow (x + \varepsilon_1 \cdot f(x)) + \varepsilon_2 \cdot g(x + \varepsilon_1 \cdot f(x)) =$$

$$x + \varepsilon_1 \cdot f(x) + \varepsilon_2 \cdot g(x) + \varepsilon_1 \cdot \varepsilon_2 \cdot g'(x) \cdot f(x) + \text{quadratic terms.}$$

- If we then apply the inverses to  $x \rightarrow x + \varepsilon_1 \cdot f(x)$  and  $x \rightarrow x + \varepsilon_2 \cdot g(x)$ , the linear terms disappear, we get:

$$x \rightarrow x + \varepsilon_1 \cdot \varepsilon_2 \cdot \{f, g\}(x), \text{ where } \{f, g\} \stackrel{\text{def}}{=} f'(x) \cdot g(x) - f(x) \cdot g'(x).$$

- Thus, if  $f(x) \in A$  and  $g(x) \in A$ , then  $\{f, g\}(x) \in A$ .
- The expression  $\{f, g\}$  is known as the *Poisson bracket*.

## 127. Why Fractional Linear (cont-d)

- Let's expand any function  $f(x)$  in Taylor series:

$$f(x) = a_0 + a_1 \cdot x + \dots$$

- If  $k$  is the first non-zero term in this expansion, we get

$$f(x) = a_k \cdot x^k + a_{k+1} \cdot x^{k+1} + a_{k+2} \cdot x^{k+2} + \dots$$

- For every  $\lambda$ , the algebra  $A$  also contains

$$\lambda^{-k} \cdot f(\lambda \cdot x) = a_k \cdot x^k + \lambda \cdot a_{k+1} \cdot x^{k+1} + \lambda^2 \cdot a_{k+2} \cdot x^{k+2} + \dots$$

- In the limit  $\lambda \rightarrow 0$ , we get  $a_k \cdot x^k \in A$ , hence  $x^k \in A$ .
- Thus,  $f(x) - a_k \cdot x^k = a_{k+1} \cdot x^{k+1} + \dots \in A$ .
- We can similarly conclude that  $A$  contains all the terms  $x^n$  for which  $a_n \neq 0$  in the original Taylor expansion.

## 128. Why Fractional Linear (cont-d)

- Since  $g(x) = 1 \in A$ , for each  $f \in A$ , we have

$$\{f, 1\} = f'(x) \cdot 1 + f(x) \cdot q' = f'(x) \in A.$$

- Thus, for each  $k$ , if  $x^k \in A$ , we have  $(x^k)' = k \cdot x^{k-1} \in A$  hence  $x^{k-1} \in A$ , etc.

- Thus, if  $x^k \in A$ , all smaller power are in  $A$  too.

- In particular, this means that if  $x^k \in A$  for some  $k \geq 3$ , then we have  $x^3 \in A$  and  $x^2 \in A$ ; thus:

$$\{x^3, x^2\} = (x^3)' \cdot x^2 - x^3 \cdot (x^2)' = 3 \cdot x^2 \cdot x^2 - x^3 \cdot 2 \cdot x = x^4 \in A.$$

- In general, once  $x^k \in A$  for  $k \geq 3$ , we get

$$\begin{aligned}\{x^k, x^2\} &= (x^k)' \cdot x^2 - x^k \cdot (x^2)' = k \cdot x^{k-1} \cdot x^2 - x^k \cdot 2 \cdot x = \\ &= (k-2) \cdot x^{k+1} \in A \text{ hence } x^{k+1} \in A.\end{aligned}$$

- So, by induction,  $x^k \in A$  for all  $k$ .

## 129. Why Fractional Linear (cont-d)

- If  $x^k \in A$  for some  $k \geq 3$ , then  $x^k \in A$  for all  $k$ .
- Thus,  $A$  is infinite-dimensional – which contradicts to our assumption that  $A$  is finite-dimensional.
- So, we cannot have Taylor terms of power  $k \geq 3$ ; therefore we have:

$$x \rightarrow x + \varepsilon \cdot (a_0 + a_1 \cdot x + a_2 \cdot x^2).$$

- This corresponds to an infinitesimal fractional-linear transformation

$$\begin{aligned} x &\rightarrow \frac{\varepsilon \cdot A + (1 + \varepsilon \cdot B) \cdot x}{1 + \varepsilon \cdot D \cdot x} = \\ &(\varepsilon \cdot A + (1 + \varepsilon \cdot B) \cdot x) \cdot (1 - \varepsilon \cdot D \cdot x) + o(\varepsilon) = \\ &x + \varepsilon \cdot (A + (B - D) \cdot x - D \cdot x^2). \end{aligned}$$

- So, to match, we need

$$A = a_0, \quad D = -a_2, \quad \text{and} \quad B = a_1 - a_2.$$

## 130. Why Fractional Linear: Final Part

- We concluded that every infinitesimal transformation is fractionally linear.
- Every transformation is a composition of infinitesimal ones.
- Composition of fractional-linear transformations is fractional linear.
- Thus, all transformations are fractional linear.

## 131. Pooling: General Part of the Two Proofs

- Let us first prove that the optimal operation  $*_{\text{opt}}$  is itself scale-invariant:  $R_{\lambda}(*_{\text{opt}}) = *_{\text{opt}}$  for all  $\lambda > 0$ .
- The fact that  $*_{\text{opt}}$  is optimal means that  $* \preceq *_{\text{opt}}$  for all  $*$ .
- In particular,  $R_{\lambda^{-1}}(*) \preceq *_{\text{opt}}$  for all  $*$ .
- Due to scale-invariance of the optimality criterion, this implies that  $* \preceq R_{\lambda}(*_{\text{opt}})$  for all  $*$ .
- Thus, the operation  $R_{\lambda}(*_{\text{opt}})$  is also optimal.
- But since the optimality criterion is final, there is only one optimal operation, so  $R_{\lambda}(*_{\text{opt}}) = *_{\text{opt}}$ .
- Scale-invariance is proven.
- Shift-invariance is proven similarly.
- For Proposition 2, we can similarly prove that the optimal  $*$  is weakly shift-invariant:  $W_{a_0}(*_{\text{opt}}) = *_{\text{opt}}$ .

## 132. Proof of Proposition 1

- Let  $a * b$  be the optimal combination operation.
- We have shown that this operation is scale-invariant and shift-invariant.
- Let us prove that it has one of the above two forms.
- For every pair  $(a, b)$ , we can have three different cases:  $a = b$ ,  $a < b$ , and  $a > b$ .
- Let us consider them one by one.
- Let us first consider the case when  $a = b$ .
- Let us denote  $v \stackrel{\text{def}}{=} 1 * 1$ .
- From scale-invariance with  $\lambda = 2$ , from  $1 * 1 = v$ , we get  $2 * 2 = 2v$ .
- From shift-invariance with  $s = 1$ , from  $1 * 1 = v$ , we get  $2 * 2 = v + 1$ .

### 133. Proof of Proposition 1 (cont-d)

- Thus,  $2v = v + 1$ , hence  $v = 1$ , and  $1 * 1 = 1$ .
- For  $a > 0$ , by applying scale-invariance with  $\lambda = a$  to the formula  $1 * 1 = 1$ , we get  $a * a = a$ .
- For  $a = 0$ , if we denote  $c \stackrel{\text{def}}{=} 0 * 0$ , then, by applying shift-invariance with  $s = 1$  to  $0 * 0 = c$ , we get

$$1 * 1 = c + 1.$$

- Since we already know that  $1 * 1 = 1$ , this means that  $c + 1 = 1$  and thus, that  $c = 0$ , i.e., that  $0 * 0 = 0$ .
- So, for all  $a \geq 0$ , we have  $a * a = a$ .
- In this case,  $\min(a, a) = \max(a, a) = a$ , so we have  $a * a = \min(a, a)$  and  $a * a = \max(a, a)$ .
- Let us now consider the case when  $a < b$ . In this case,  $b - a > 0$ .

## 134. Proof of Proposition 1 (cont-d)

- Let us denote  $t \stackrel{\text{def}}{=} 0 * 1$ .
- By applying scale-invariance with  $\lambda = b - a > 0$  to the formula  $0 * 1 = t$ , we get  $0 * (b - a) = (b - a) \cdot t$ .
- Now, by applying shift-invariance with  $s = a$  to this formula, we get  $a * b = (b - a) \cdot t + a$ .
- To find possible values of  $t$ , let us take into account that the combination operation should be associative.
- This means, in particular, that for all possible triples  $a, b$ , and  $c$  for which we have  $a < b < c$ , we must have

$$a * (b * c) = (a * b) * c.$$

- Since  $b < c$ , by the above formula, we have  $b * c = (c - b) * t + b$ .
- Since  $t \geq 0$ , we have  $b * c \geq b$  and thus,  $a < b * c$ .

## 135. Proof of Proposition 1 (cont-d)

- So, to compute  $a * (b * c)$ , we can also use the above formula, and get  $a * (b * c) = (b * c - a) \cdot t + a =$

$$((c - b) \cdot t + b) \cdot t + a = c \cdot t^2 + b \cdot (t - t^2) + a.$$

- Let us restrict ourselves to the case when  $a * b < c$ .
- In this case, the general formula implies that

$$(a * b) * c = (c - a * b) \cdot t + a * b = (c - ((b - a) \cdot t + a)) \cdot t + (b - a) \cdot t + a.$$

- So  $(a * b) * c = c \cdot t + b \cdot (t - t^2) + a \cdot (1 - t)^2$ .
- Due to associativity, the two formulas must coincide for all  $a$ ,  $b$ , and  $c$  for which  $a < b < c$  and  $c > a * b$ .
- These two linear expressions must be equal for all sufficiently large values of  $c$ .
- Thus, the coefficients at  $c$  must be equal, i.e., we must have  $t = t^2$ .

## 136. Proof of Proposition 1 (cont-d)

- From  $t = t^2$ , we conclude that  $t - t^2 = t \cdot (1 - t) = 0$ , so either  $t = 0$  or  $1 - t = 0$  (in which case  $t = 1$ ).
- If  $t = 0$ , then the above formula has the form  $a * b = a$ , i.e., since  $a < b$ , the form  $a * b = \min(a, b)$ .
- If  $t = 1$ , then the above formula has the form

$$a * b = (b - a) + a = b.$$

- Since  $a < b$ , we get  $a * b = \max(a, b)$ .
- If  $a > b$ , then, by commutativity, we have  $a * b = b * a$ , where now  $b < a$ .
- So, either we have  $a * b = \min(a, b)$  for all  $a$  and  $b$ , or we have  $a * b = \max(a, b)$  for all  $a$  and  $b$ .
- The proposition is proven.

## 137. Proof of Proposition 2

- Let  $a * b$  be the optimal combination operation.
- We have proven that this operation is scale-invariant and weakly shift-invariant.
- This means that  $a * b = c$  implies  $(a + s) * (b + s) = c + f(s)$ .
- Let us prove that the optimal operation  $*$  has one of the above four forms.
- Let us first prove that  $0 * 0 = 0$ .
- Indeed, let  $s$  denote  $0 * 0$ .
- Due to scale-invariance,  $0 * 0 = s$  implies that  $(2 \cdot 0) * (2 \cdot 0) = 2s$ , i.e., that  $0 * 0 = 2s$ .
- So, we have  $s = 2s$ , hence  $s = 0$  and  $0 * 0 = 0$ .
- Similarly, if we denote  $v \stackrel{\text{def}}{=} 1 * 1$ , then, due to scale-invariance with  $\lambda = a$ ,  $1 * 1 = v$  implies that  $a * a = v \cdot a$ .

## 138. Proof of Proposition 2 (cont-d)

- On the other hand, due to weak shift-invariance with  $a_0 = a$ ,  $0 * 0 = 0$  implies that  $a * a = f(a)$ .
- Thus, we conclude that  $f(a) = v \cdot a$ .
- Let us now consider the case when  $a < b$  and, thus,  $b - a > 0$ .
- Let us denote  $t \stackrel{\text{def}}{=} 0 * 1$ .
- From scale-invariance with  $\lambda = b - a$ , from  $0 * 1 = t \geq 0$ , we get  $0 * (b - a) = t \cdot (b - a)$ .
- From weak shift-invariance with  $a_0 = a$ , we get  $a * b = t \cdot (b - a) + v \cdot a$ , i.e.,  $a * b = t \cdot b + (v - t) \cdot a$ .
- The combination operation should be associative:  $a * (b * c) = (a * b) * c$ .
- When  $b < c$ , we have  $b * c = t \cdot c + (v - t) \cdot b$ .

## 139. Proof of Proposition 2 (cont-d)

- We know that  $t \geq 0$ . This means that we have either  $t > 0$  and  $t = 0$ .
- Let us first consider the case when  $t > 0$ .
- In this case, for sufficiently large  $c$ , we have  $b * c > a$ .
- So, by applying the above formula to  $a$  and  $b * c$ , we conclude that

$$a*(b*c) = t*(b*c) + (v-t)*a = t^2*c + t*(v-t)*b + (v-t)*a.$$

- For sufficient large  $c$ , we also have  $a * b < c$ .
- In this case, the general formula implies that
$$(a*b)*c = (t*b + (v-t)*a)*c = t*c + t*(v-t)*b + (v-t)^2*a.$$
- Due to associativity, these formulas must coincide for all  $a$ ,  $b$ , and  $c$  for which

$$a < b < c, \quad c > a * b, \quad \text{and} \quad b * c > a.$$

## 140. Proof of Proposition 2 (cont-d)

- These two linear expressions must be equal for all sufficiently large values of  $c$ .
- So, the coefficients at  $c$  must be equal, i.e., we must have  $t = t^2$ .
- From  $t = t^2$ , we conclude that  $t - t^2 = t \cdot (1 - t) = 0$ .
- Since we assumed that  $t > 0$ , we must have  $t - 1 = 0$ , i.e.,  $t = 1$ .
- The coefficients at  $a$  must also coincide, so we must have  $v - t = (v - t)^2$ , hence either  $v - t = 0$  or  $v - t = 1$ .
- In the first case, the above formula becomes  $a * b = b$ , i.e.,  $a * b = \max(a, b)$  for all  $a \leq b$ .
- Since the operation  $*$  is commutative, this equality is also true for  $b \leq a$  and is, thus, true for all  $a$  and  $b$ .

## 141. Proof of Proposition 2 (cont-d)

- In the second case, the above formula becomes  $a * b = a + b$  for all  $a \leq b$ .
- Due to commutativity, this formula holds for all  $a, b$ .
- Let us now consider the case when  $t = 0$ .
- In this case, the above formula takes the form  $a * b = (v - t) \cdot a$ .
- Here,  $a * b \geq 0$ , thus  $v - t \geq 0$ .
- If  $v - t = 0$ , this implies that  $a * b = 0$  for all  $a \leq b$  and thus, due to commutativity, for all  $a$  and  $b$ .
- Let us now consider the remaining case when  $v - t > 0$ .
- In this case, if  $a < b < c$ , then for sufficiently large  $c$ , we have  $a * b < c$ , hence

$$(a*b)*c = (v-t) \cdot (a*b) = (v-t) \cdot ((v-t) \cdot a) = (v-t)^2 \cdot a.$$

## 142. Proof of Proposition 2 (cont-d)

- On the other hand, here  $b * c = (v - t) \cdot b$ .
- So, for sufficiently large  $b$ , we have  $(v - t) \cdot b > a$ , thus

$$a * (b * c) = (v - t) \cdot a.$$

- Due to associativity, we have  $(v - t)^2 \cdot a = (v - t) \cdot a$ , hence  $(v - t)^2 = v - t$ .
- Since  $v - t > 0$ , we have  $v - t = 1$ .
- In this case, the above formula takes the form  $a * b = a = \min(a, b)$  for all  $a \leq b$ .
- Thus, due to commutativity, we have  $a * b = \min(a, b)$  for all  $a$  and  $b$ .
- We have thus shown that the combination operation indeed has one of the four forms.
- Proposition 2 is therefore proven.
