## 1. Formulation of the problem

- For dynamic quantities, we may have two different objectives:
  - We may be interested in knowing the *average* value of the measured quantity.
  - We may want to know the actual dependence of the measured quantity on space location and/or time.
- Meteorological example:
  - to study general weather patterns, we need average wind speed;
  - to guide airplanes, we need to know the exact wind speed at different locations.

## 2. Measuring the average value: case of ideal measuring instrument

- *Case description:* measurement errors are negligible.
- *Details:* we measure the values  $x_1, \dots, x_n$  at  $n$  different locations, and estimate

$$E \stackrel{\text{def}}{=} \frac{x_1 + \dots + x_n}{n}.$$

- *Notation:* let  $\sigma_0$  be the standard deviation of the difference  $x_i - x_0$ .
- *Conclusion:* for the average, standard deviation is  $\sigma_0/\sqrt{n}$ , so error bound is  $\Delta = k_0 \cdot \sigma_0/\sqrt{n}$ , where:
  - 95% confidence corresponds to  $k_0 = 2$ ,
  - 99.9% corresponds to  $k_0 = 3$ .

- *Recommendation:* to get error  $\leq \Delta_0$ , we need

$$n \approx \frac{k_0^2 \cdot \sigma_0^2}{\Delta_0^2}.$$

### 3. Measuring the average value: case of realistic measuring instrument

- *Case description:* we have random error with st. dev.  $\sigma$  and a systematic error  $\Delta_s$  bounded by  $\Delta$ :  $|\Delta_s| \leq \Delta$ .
- *Resulting random error component in measuring average:* st. dev.  $\sigma_t \stackrel{\text{def}}{=} \sqrt{\sigma^2 + \sigma_0^2}$ .
- *Resulting overall error bound:*

$$\Delta_0 = \Delta + k_0 \cdot \frac{\sigma_t}{\sqrt{n}}.$$

- *Observation:* situation is similar to static measurements.
- *Conclusion:* we have use the recommendations from the static case.
- *Example:* to achieve accuracy  $\Delta_0$  with the minimal cost, take  $\Delta \approx (1/3) \cdot \Delta_0$ .

## 4. Measuring the actual dependence: formulation of the problem.

- We are often interested in the actual dependence of a quantity on space and/or time.
- *Possible situations:*
  - A quantity that only depends on time  $t$ .
  - *Example:* temperature at a given location.
  - A quantity that only depends on the spatial location  $t = (t_1, t_2)$  or  $t = (t_1, t_2, t_3)$ .
  - *Example:* density inside the Earth.
  - A quantity that depends both on time  $t_1$  and on the spatial location  $(t_2, \dots)$ .
  - *Example:* temperature in the atmosphere.
- *General description:* we measure  $x(t)$  for different

$$t = (t_1, \dots, t_d).$$

## 5. Approximation inaccuracy

- *Fact:* we only measure  $x(t)$  at  $n$  different values  $t^{(1)}, \dots, t^{(n)}$ .
- To get values  $x(t)$  for  $t \neq t^{(i)}$ , we use interpolation.
- *Main assumptions:* we assume that:  $x(t)$  is smooth, and we know the bound  $g$  on the rate of change:

$$|x(t) - x(t')| \leq g \cdot \|t - t'\|.$$

- *Conclusion:* to minimize the approximation error  $|x(t) - x(t^{(i)})|$ , we must minimize the distance  $\|t - t^{(i)}\|$ .
- If each value  $t$  is within distance  $\rho$  from one of  $t^{(i)}$ , then  $n$  balls centered in  $t^{(i)}$  cover the domain of volume  $V$ .
- Hence,  $V \leq n \cdot c \cdot \rho^d$ , and  $\rho \geq c \cdot (V/n)^{1/d}$ .
- For a grid:  $\rho \approx c_1 \cdot (V/n)^{1/d}$ .
- *Conclusion:* approximation error is  $d \cdot c_1 \cdot (V/n)^{1/d}$ .
- *Overall error:*  $\Delta + d \cdot c_1 \cdot (V/n)^{1/d}$ .

## 6. Trade-off problems for engineering and science: formulation

- In engineering applications:
  - we know the overall accuracy  $\Delta_0$ , and
  - we want to minimize the cost of the resulting measurement:

Minimize  $n \cdot F(\Delta) \rightarrow \min_{\Delta, n}$  under the constraint  $\Delta + \frac{g_0}{n^{1/d}} = \Delta_0$ .

- In scientific applications:
  - we are given the cost  $F_0$ , and
  - the problem is to achieve the highest possible accuracy within this cost:

Minimize  $\Delta + \frac{g_0}{n^{1/d}} \rightarrow \min_{\Delta, n}$  under the constraint  $n \cdot F(\Delta) = F_0$ .

## 7. Solutions

- *Reminder:* basic cost model  $F(\Delta) = c/\Delta$ .

Minimize  $n \cdot F(\Delta) \rightarrow \min_{\Delta, n}$  under the constraint  $\Delta + \frac{g_0}{n^{1/d}} = \Delta_0$ .

- *Solution for engineering situations:*

$$\Delta_{\text{opt}} = \frac{1}{d+1} \cdot \Delta_0; \quad n_{\text{opt}} = \left( \frac{g_0}{\Delta_0} \cdot \frac{d+1}{d} \right)^d.$$

Minimize  $\Delta + \frac{g_0}{n^{1/d}} \rightarrow \min_{\Delta, n}$  under the constraint  $n \cdot F(\Delta) = F_0$ .

- *Solution for science situations:*

$$n_{\text{opt}} = \left( \frac{F_0}{c} \cdot \frac{g_0}{d} \right)^{d/(d+1)}; \quad \Delta_{\text{opt}} = \frac{n_{\text{opt}} \cdot c}{F_0}.$$

- *Observation:* the optimal trade-off is when both error components are of approximately the same size.
- *Comment:* this is similar to the static case.

## 8. Case of non-smooth processes

- *Example of a non-smooth process:* Brownian motion:

$$|x(t) - x(t')| \leq \|t - t'\|^{1/2}.$$

- *General (fractal) case:*  $|x(t) - x(t')| \leq \|t - t'\|^\beta$ .
- For  $n$  measurements, distance  $\rho$  is  $\approx (V/n)^{1/d}$ , so approximation error is  $\sim (V/n)^{\beta/d}$ .

- *Overall error:*  $\Delta + \frac{g_\beta}{n^{\beta/d}}$ , where  $g_\beta \stackrel{\text{def}}{=} C \cdot d^{\beta/2} \cdot \frac{1}{2^{\beta/d}} \cdot V^{\beta/d}$ .

- *Trade-off problems for engineering:*

$$\text{Min } n \cdot F(\Delta) \text{ under the constraint } \Delta + \frac{g_\beta}{n^{\beta/d}} = \Delta_0.$$

- *Trade-off problems for science:*

$$\text{Min } \Delta + \frac{g_\beta}{n^{\beta/d}} \text{ under the constraint } n \cdot F(\Delta) = F_0.$$

- *Observation:* formulas same as in the smooth case, with  $d' \stackrel{\text{def}}{=} d/\beta$  instead of  $d$ .

## 9. Case of non-smooth processes: solutions

- *Case*: basic cost model  $F(\Delta) = c/\Delta$ .

- *Engineering problem – reminder*:

$$\text{Min } n \cdot F(\Delta) \text{ under the constraint } \Delta + \frac{g_\beta}{n^{\beta/d}} = \Delta_0.$$

- *Engineering problem – solution*:

$$\Delta_{\text{opt}} = \frac{\beta}{d + \beta} \cdot \Delta_0; \quad n_{\text{opt}} = \left( \frac{g_\beta}{\Delta_0} \cdot \frac{d + \beta}{d} \right)^d.$$

- Min  $\Delta + \frac{g_\beta}{n^{\beta/d}}$  under the constraint  $n \cdot F(\Delta) = F_0$ .

- *Science problem – solution*:

$$n_{\text{opt}} = \left( \frac{F_0}{c} \cdot \frac{g_\beta}{d} \right)^{d/(d+\beta)}; \quad \Delta_{\text{opt}} = \frac{n_{\text{opt}} \cdot c}{F_0}.$$

- *Comment*: in the optimal trade-off, both error components are of approximately the same value.

## 10. Case of more accurate measuring instruments

- *Reminder:* the cost  $F(\Delta)$  of a measurement depends on its accuracy as

$$F(\Delta) = \frac{c}{\Delta^\alpha}.$$

- Once we go beyond the basic cost model  $\alpha = 1$ , we get  $\alpha = 3$ .
- Then, as we increase accuracy, we switch to a different value  $\alpha$ .
- *Solution:* in the engineering case, the optimal accuracy is

$$\Delta_{\text{opt}} = \frac{\alpha}{\alpha + 2} \cdot \Delta_0.$$

- *Example:* for  $\alpha = 3$ , we have

$$\Delta_{\text{opt}} = \frac{3}{5} \cdot \Delta_0.$$

## 11. Conclusions

- *General heuristic:* the optimal is when error components are approximately of the same size.
- To measure a single quantity, take  $\Delta = \frac{1}{3} \cdot \Delta_0$ .
- To reconstruct all the values  $x(t)$  of a smooth quantity  $x$  depending on  $d$  parameters, take  $\Delta = \frac{1}{d+1} \cdot \Delta_0$ .
- To reconstruct all the values  $x(t)$  of a non-smooth quantity  $x$  depending on  $d$  parameters, take  $\Delta = \frac{\beta}{d+\beta} \cdot \Delta_0$ .
- Here  $\beta$  is the exponent of the power law that describes how the difference  $x(t + \Delta t) - x(t)$  changes with  $\|\Delta t\|$ .
- For more accurate measuring instruments, when  $F(\Delta) = \frac{c}{\Delta^3}$ , we should take  $\Delta = \frac{3}{5} \cdot \Delta_0$ .
- In general, if  $F(\Delta) = \frac{c}{\Delta^\alpha}$ , take  $\Delta = \frac{\alpha}{\alpha+2} \cdot \Delta_0$ .
