## 1. Need to Help People Make Decisions

- In many practical situations, we need to make a decision.
- In other words, we need to select an alternative which is, for us, better than all other possible alternatives.
- If the set of alternatives is small, we can easily make such a decision: indeed,
  - we can easily compare each alternative with every other one, and,
  - based on these comparisons, decide which one is better.
- However, when the number of alternatives becomes large, we have trouble making decisions.

## 2. Need to Help People Make Decisions (cont-d)

- Even in simple situations, when we are looking for cereal in a supermarket:
  - there are usually so many selections
  - that we just ignore most of them and go with a familiar one – instead of the optimal one.
- The situation is even more complicated if:
  - we are trying to make a decision not on behalf of ourselves,
  - but rather on behalf of a company or a community.

### 3. Need to Help People Make Decisions (cont-d)

- In this case, even comparing two alternatives is not easy:
  - it requires taking into account interests of different people involved,
  - so the decision making process becomes even more complicated.

## 4. Traditional Approach to Decision Making: the Notion of Utility

- The traditional approach to decision making was originally motivated by the idea of money.
- When money was invented, it was a revolutionary idea that made economic exchange much easier.
- Before money was invented, people exchanged goods by barter: chicken for a shirt, jewelry for boots, etc.
- Thus, to make a proper decision, every person needed to be able to compare every two items with each other:
  - how many chickens is this person willing to exchange for a shirt,
  - how many boots for a golden earring, etc.
- For  $n$  goods, we have  $\frac{n \cdot (n - 1)}{2} \approx \frac{n^2}{2}$  possible pairs.

## 5. The Notion of Utility (cont-d)

- So, each person had to have in mind a table of  $n^2/2$  numbers.
- With money as a universally accepted means of exchange, all the person needs to do is to decide:
  - for each of  $n$  items,
  - how much he or she is willing to pay for 1 unit.
- So, to successfully make decisions, it is sufficient to know  $n$  numbers – the values of each of  $n$  items; then:
  - even when we want to barter,
  - we can easily decide how many chickens are worth a shirt:
  - it is sufficient to divide the price of a shirt by the price of a chicken.

## 6. The Notion of Utility (cont-d)

- A similar idea can be used to compare different alternatives.
- All we need is to have a numerical scale, i.e., we need a 1-parametric family of “standard” alternatives
  - whose quality increases
  - with the increase in the value of the parameter.
- This can be the money amount.
- Alternatively, this can be the probability  $p$  of a lottery in which we get something very good.
- The larger the probability, the more preferable the lottery.

## 7. The Notion of Utility (cont-d)

- Then, instead of comparing every alternative  $a$  with every other alternative, we simply compare:
  - every alternative with
  - alternatives on the selected scale.
- Thus, for each  $a$ , we find the numerical value of the standard alternative which is equivalent to  $a$ .
- This numerical value is known as the *utility*  $u(a)$  of a given alternative  $a$ .

## 8. The Notion of Utility (cont-d)

- In terms of utility, an alternative  $a$  is better than the alternative  $a'$  if and only if  $u(a) > u(a')$ ; thus:
  - once we have found the utility  $u(a)$  of each alternative,
  - then it is easy to predict which alternative the person will select:
  - he/she will select the alternative for which the utility  $u(a)$  is the largest possible.

## 9. How to Actually Find the Utility

- The fastest way to find the utility of a given alternative  $a$  based on binary comparisons is to use bisection.
- Usually, we have an a priori lower bound and an a priori upper bound for the desired utility  $u(a)$ :  $\underline{u} \leq u(a) \leq \bar{u}$ .
- In other words, we know that the desired utility  $u(a)$  is somewhere in the interval  $[\underline{u}, \bar{u}]$ .
- In this procedure, we will narrow down this interval.
- Once an interval is given, we can:
  - compute its midpoint  $\tilde{u} = \frac{\underline{u} + \bar{u}}{2}$  and
  - compare  $a$  with the corresponding standard alternative  $s(\tilde{u})$ .
- If  $a$  is exactly equivalent to  $s(\tilde{u})$ , then  $u(a) = \tilde{u}$ .

## 10. How to Actually Find the Utility (cont-d)

- However, such exact equivalences are rare; in most cases, we will find out that:
  - either  $a$  is better than  $s(\tilde{u})$ ; we will denote it by  $s(\tilde{u}) < a$ ; or
  - the standard alternative is better:  $a < s(\tilde{u})$ .
- In the first case, the preference  $s(\tilde{u}) < a$  means that

$$\tilde{u} < u(a).$$

- Thus, we know that  $u(a) \in [\tilde{u}, \bar{u}]$ .
- In other words, we have a new interval containing the desired utility.
- We can obtain this new interval if we replace the previous lower bound  $\underline{u}$  with the new lower bound  $\tilde{u}$ .

## 11. How to Actually Find the Utility (cont-d)

- In the second case, the preference  $a < s(\tilde{u})$  means that

$$u(a) < \tilde{u}.$$

- Thus, we know that  $u(a) \in [\underline{u}, \tilde{u}]$ .
- In other words, we have a new interval containing the desired utility.
- We can obtain this new interval if we replace the previous upper bound  $\bar{u}$  with the new upper bound  $\tilde{u}$ .
- In both cases, the width of the interval is decreased by a factor of 2.
- Then, we can repeat this procedure, and in  $k$  steps, we get  $u(a)$  with accuracy  $2^{-k}$ .
- For example, in 7 steps, we get an accuracy of 1%.

## 12. Need to Take Fuzziness into Account

- The above procedure works well if a person is absolutely sure about his/her preferences.
- In practice, we are often not 100% sure about our preferences.
- This is especially true when we compare alternatives of similar value.
- It is reasonable to describe this uncertainty in fuzzy terms.
- For example, if we use money as a standard scale, then for each alternative  $a$ ,
  - instead of having a single amounts of money equivalent to this item,
  - we may have different amounts with different degree of certainty.

## 13. Need to Take Fuzziness into Account (cont-d)

- In other words,
  - instead of the above crisp model, in which a person has an exact utility value  $u(a)$  for each  $a$ ,
  - for each person and for each alternative  $a$ , we have a membership function  $\mu_a(u)$ ,
  - this function describes, for each possible value  $u$ , to what extent  $s(u)$  is equivalent to  $a$ .

## 14. How to Elicit Fuzzy Utility: a Reasonable Idea

- We know how to elicit crisp utility  $u(a)$  of a given alternative  $a$ : we need to compare:
  - the alternative  $a$
  - with different values  $u_0$  of the scale.
- In the case of fuzzy utility, it is reasonable to apply the same procedure.
- The only difference is that:
  - now, since the utility value  $u(a)$  is fuzzy,
  - this comparison will not lead to a crisp “yes” - “no” answer;
  - instead, we will get a fuzzy answer – the degree to which it is possible that  $a$  is better than  $u_0$ ,
  - and, if needed, the degree to which it is possible that  $a$  is worse than  $u_0$ .

## 15. Remaining Open Problems

- In the crisp case, we can determine the utility value  $u(a)$  from the results of the user's comparisons.
- To deal with the more realistic fuzzy case, we need:
  - to extract the fuzzy utility
  - from the fuzzy answers to different comparisons.
- This is the question that we deal with in this talk.
- Interestingly, it turns out that in this context, intuitionistic fuzzy degrees naturally appear.
- In other words, instead of a single degree of confidence in each statement, we now get *two* degrees:
  - the degree to which this statement is true, and
  - the degree to which this statement is false.
- These degrees do not add up to 1.

## 16. What If We Compare the Alternative $a$ with a Fixed Value $u_0$ on the Utility Scale?

- In the crisp case, each alternative  $a$  is equivalent to a single number  $u(a)$  on the utility scale.
- In general, the utility of an alternative is characterized:
  - not by a single number,
  - but rather with a membership function  $\mu_a(u)$ .
- This function describes, for each value  $u$  from the utility scale, to what extent  $a$  is equivalent to  $u$ .
- What will happen is we compare the alternative  $a$  to a value  $u_0$  on the utility scale?
- In the crisp case, the changes that  $a$  is exactly equivalent to  $a_0$  are slim.
- So, we have either  $a < u_0$  or  $u_0 < a$ .

## 17. What If We Compare $a$ with $u_0$ (cont-d)

- Thus, we can ask whether  $a$  is better than  $u_0$ , or we can ask whether  $u_0$  is better than  $a$ .
- Whatever question we ask, we get the exact same information.
- Let us first consider the question of whether  $a$  is better than  $u_0$ , i.e., whether  $u_0 < a$ .
- How can we extend this to the fuzzy case?
- It is convenient to take into account that:
  - while from math. viewpoint,  $<$  is a relation,
  - and in mathematics, relations usually treated differently than functions,
  - from the computational viewpoint,  $<$  a function.

## 18. What If We Compare $a$ with $u_0$ (cont-d)

- Similarly:
  - the addition  $+$  is a function that takes two numbers and returns a number which is their sum,
  - the relation  $<$  is a function that takes two numbers and returns a boolean value: true or false.
- Since  $<$  can be naturally treated as function:
  - the question of how to extend this to fuzzy
  - becomes a particular case of a more general question:
    - how to extend functions to fuzzy?
- This extension is well known, it is described by Zadeh's extension principle.
- Let us recall how this principle is usually derived.

## 19. Zadeh's Extension Principle and How It Is Usually Derived

- Suppose that:
  - we have a function  $y = f(x_1, \dots, x_n)$  of  $n$  real-valued variables, and
  - we have fuzzy information about the values  $x_1, \dots, x_n$ ,
  - i.e., we know membership functions  $\mu_1(x_1), \dots, \mu_n(x_n)$  that describes our knowledge about the inputs  $x_1, \dots, x_n$ .
- Based on this information, what do we know about  $y = f(x_1, \dots, x_n)$ ?
- Intuitively,  $Y$  is a possible value of the variable  $y$  if there exists values  $X_1, \dots, X_n$  for which:
  - the value  $X_1$  is a possible value of  $x_1$  *and* ...
  - *and*  $X_n$  is a possible value of  $x_n$
  - *and*  $Y = f(X_1, \dots, X_n)$ .

## 20. Zadeh's Extension Principle (cont-d)

- We know the degrees  $\mu_i(X_i)$  to which each each real number  $X_i$  is a possible values of the input  $x_i$ .
- We need to combine these degrees into our degree of confidence in a composite and-statement.
- For this, we can use an “and”-operation (t-norm).
- The simplest of them is  $\min(a, b)$ .
- Thus, for each  $(X_1, \dots, x_n)$  for which  $Y = f(X_1, \dots, X_n)$ , our degree of confidence is the above and-statement is

$$\min(\mu_1(X_1), \dots, \mu_n(X_n)).$$

- The existential quantifier “there exists” is, in effect, an “or”.
- It means that either this property is true for one tuple, or for another tuple, etc.

## 21. Zadeh's Extension Principle (cont-d)

- Thus:
  - to find the degree to which the value  $Y$  is possible,
  - we need to apply an “or”-operation (t-conorm)
  - to the degrees of confidence of the corresponding “and”-statements.
- The simplest “or”-operation is  $\max(a, b)$ .
- Thus, we arrive at the following formula for the degree  $\mu(Y)$  to which  $Y$  is a possible value of the variable  $y$ :
$$\mu(Y) = \max\{\min(\mu_1(X_1), \dots, \mu_n(X_n)) : f(X_1, \dots, X_n) = Y\}.$$
- This formula – first proposed by L. Zadeh himself – is known as *Zadeh's extension principle*.

## 22. Let Us Apply Zadeh's Extension Principle to Our Problem: Resulting Formulas

- In our case, we have a Boolean-valued function  $f(x_1, x_2) = (x_1 < x_2)$  of  $n = 2$  real-valued variables.
- We compare an alternative  $a$  with fuzzy utility  $\mu_a(u)$  with a crisp value  $u_0$ .
- Zadeh's extension principle takes the following form:
  - for the value  $y = \text{“true”}$ , the degree  $\mu_+(a < u_0)$  that the statement  $a < u_0$  is true is equal to

$$\mu_+(a < u_0) = \max(\mu_a(u) : u < u_0);$$

- for the value  $y = \text{“false”}$ , the degree  $\mu_-(a < u_0)$  that the statement  $a < u_0$  is false is equal to

$$\mu_-(a < u_0) = \max(\mu_a(u) : u \geq u_0).$$

## 23. Let Us Analyze the Resulting Formulas

- In fuzzy logic negation is represented by  $1 - a$ .
- Thus, our degree of believe that  $A$  is false is estimated as 1 minus degree that  $A$  is true.
- So, we should expect that  $\mu_+(a < u_0) + \mu_-(a < u_0) = 1$ .
- Let us show, however, that this is not the case.
- Indeed, let us consider a typical case when  $\mu_a(u)$  is a fuzzy number, i.e., when for some value  $U$ :
  - the function  $\mu_a(u)$  increases to 1 when  $u \leq U$ , and
  - this function decreases from 1 when  $u \geq U$ .
- When  $u_0 < U$ , then the function  $\mu_a(u)$  is increasing for all  $u < u_0$  and thus,  $\mu_+(a < u_0) = \mu_a(u_0)$ .
- On the other hand, since  $u_0 < U$  and for  $u = U$ , we have  $\mu_a(U) = 1$ , we get  $\mu_-(a < u_0) = 1$ ; thus:

$$\mu_+(a < u_0) + \mu_-(a < u_0) = 1 + \mu_a(u) \neq 1.$$

## 24. Analyzing the Resulting Formulas (cont-d)

- The only exception is, of course, we consider absolutely impossible values  $u$  for which  $\mu_a(u) = 0$ .
- Similarly, when  $u_0 \geq U$ , then the function  $\mu_a(u)$  is decreasing for all  $u > u_0$  and thus,

$$\mu_-(a < u_0) = \mu_a(u_0).$$

- On the other hand, since  $u_0 \geq U$  and for  $u = U$ , we have  $\mu_a(U) = 1$ , we get  $\mu_+(a < u_0) = 1$ .
- Thus, in this case too, we have

$$\mu_+(a < u_0) + \mu_-(a < u_0) = 1 + \mu_a(u) \neq 1.$$

- The only exception is absolutely impossible values  $u$  for which  $\mu_a(u) = 0$ .

## 25. So, We Get Intuitionistic Fuzzy Degrees

- In the traditional fuzzy logic:
  - the sum of degrees to which each statement is true and to which this same statement is false
  - is always equal to 1.
- This means that when we compare alternatives, we get beyond the traditional fuzzy logic.
- How can we describe where we are?
- This is not the only case when the degrees of confidence in a statement and in its negation do not add up to 1.
- To describe such cases, K. Atanassov came up with an idea of *intuitionistic fuzzy logic*.

## 26. Intuitionistic Fuzzy Degrees (cont-d)

- In this logic, for each statement, we have *two* degrees:
  - the degree to which this statement is true, and
  - the degree to which this statement is false.
- These degrees do not necessarily add to 1.
- So, the result of comparing two alternatives is an intuitionistic fuzzy degree.

## 27. What We Got Is Somewhat Different From Intuitionistic Fuzzy Logic

- There is a minor difference between what we observe and the traditional intuitionistic fuzzy logic:
  - in the intuitionistic fuzzy logic, the sum of positive and negative degrees is always  $\leq 1$ , while
  - in our case, the sum is always greater than or equal to 1.
- However, such (minor) generalization of intuitionistic fuzzy logic has been proposed in the past.
- We can reconcile the results of comparing alternatives with the traditional intuitionistic fuzzy logic.
- Indeed, in general, Zadeh's extension principle, we compute the degree to which  $y$  is a *possible* value.
- In particular,  $\mu_+(a < u_0)$  is the degree to which is possible that  $a < u_0$ .

## 28. What We Got (cont-d)

- Similarly,  $\mu_-(a < u_0)$  is a degree to which it is possible that  $a \geq u_0$ .
- Instead, we consider degrees  $n_+(a < u_0)$  and  $n_-(a < u_0)$  to which it is *necessary* that  $a < u_0$  and that  $a \geq u_0$ .
- They can be defined, as usual, as 1 minus the degree to which the opposite statement is possible.
- Then, we get

$$n_+(a < u_0) = 1 - \mu_-(a < u_0) \text{ and } n_-(a < u_0) = 1 - \mu_+(a < u_0).$$

- From the fact that  $\mu_+(a < u_0) + \mu_-(a < u_0) \geq 1$ , we can now conclude that

$$n_+(a < u_0) + n_-(a < u_0) = 2 - (\mu_+(a < u_0) + \mu_-(a < u_0)) \leq 1.$$

- Thus, the degrees of necessity are consistent with the traditional intuitionistic fuzzy logic.

## 29. Reconstructing the Original Membership F-n from the Results of Expert Elicitation

- We assume that the expert's preferences are described by a membership function  $\mu_a(u_0)$ .
- As we have mentioned, as a result of expert elicitation, we do not get this function.
- Instead, we get instead a more complex construct, in which for each possible value  $u_0$ , we get two degrees:

$$\mu_+(a < u_0) \text{ and } \mu_-(a < u_0).$$

- Interestingly, from these degrees, we can uniquely reconstruct the original membership function.

### 30. Reconstructing the Original Membership Function (cont-d)

- Indeed, as have shown:
  - when  $u_0 \leq U$ , then we have  $\mu_+(a < u_0) = \mu_a(u_0)$  and  $\mu_-(a < u_0) = 1$ ; and
  - when when  $u_0 \geq U$ , then we have  $\mu_-(a < u_0) = \mu_a(u_0)$  and  $\mu_+(a < u_0) = 1$ .
- In both cases, we thus have

$$\mu_a(u_0) = \min(\mu_+(a < u_0), \mu_-(a < u_0)).$$
