# 1. Sliced-Normal Distributions Are Efficient

- In many practical applications, it turns out to be efficient to use Sliced-Normal multi-D distributions.
- These are distributions for which log of probability density function (pdf)  $f(x_1, \dots, x_n)$  is a polynomial:

$$\ln(f(x_1, \dots, x_n)) = P(x_1, \dots, x_n), \text{ so}$$

$$f(x_1, \dots, x_n) = \exp(P(x_1, \dots, x_n)).$$

- To be more precise,  $\log(f)$  is a sum of squares of several polynomials
- This class is a natural extension of:
  - normal distributions, i.e.,
  - distributions for which the logarithm of the pdf is a quadratic polynomial.

## 2. But Why?

- The sliced-normal distributions have been empirically successful.
- However, there seems to be no convincing theoretical explanation for their empirical success.
- The main goal of this paper is to provide such an explanation.

### 3. Let Us Formulate This Problem in Precise Terms

- In principle, we can have many different probability density functions.
- The class of all the functions is infinite-dimensional.
- This means that:
  - to select a single probability density function out of all possible such functions,
  - we need to know the values of infinitely many parameters,
  - e.g., values of the pdf at points with rational coordinates.

## 4. Let Us Formulate This Problem in Precise Terms (cont-d)

- In practice, however, at any given moment of time, we only have finitely many observations.
- Based on these observations, we can determine only finitely many parameters.
- Thus, it makes sense to look for families  $F$  of probability density functions:
  - that depend on finitely many parameters  $c_1, \dots, c_m$ ,
  - i.e., on families of the type

$$F = \{f(x_1, \dots, x_n, c_1, \dots, c_m)\}_{c_1, \dots, c_m}.$$

## 5. The Dependence Should Be Continuous

- All our information about the physical world comes from measurements and from expert estimates.
- Measurements are never 100% accurate, expert estimates are even less accurate.
- So, we can only determine the values  $x_i$  and  $c_j$  with some accuracy:
  - based on these approximate values of  $x_i$  and  $c_j$ ,
  - we estimate of the value  $f(x_1, \dots, x_n, c_1, \dots, c_m)$  of the pdf.
- The more accurately we perform measurements, the more accurate should be our estimates.
- So, the dependence of  $f(x_1, \dots, x_n, c_1, \dots, c_m)$  on all its inputs  $x_i$  and  $c_j$  should be continuous.

## 6. The Dependence Should Be Differentiable

- Moreover, small inaccuracy in  $x_i$  and  $c_j$  should lead to proportionally small inaccuracy in the value of

$$f(x_1, \dots, x_n, c_1, \dots, c_m).$$

- Thus, the function  $f(x_1, \dots, x_n, c_1, \dots, c_m)$  should be *differentiable*.

## 7. The Class of Distributions Should Be Closed Under Fusion

- We only know the *probability* of different tuples

$$x = (x_1, \dots, x_n).$$

- This means that we do not know which of the tuples describe the corresponding real-life situation.
- In other words, the fact that we have a probabilistic knowledge means that our knowledge is incomplete.
- It is therefore desirable to gain additional knowledge about the situation:
  - either by performing additional measurements,
  - or by requesting additional expert estimates.

## 8. Closed Under Fusion (cont-d)

- This additional knowledge usually comes in the form of a probability distribution; once we have it:
  - we need to fuse it
  - with the distribution describing our original knowledge.
- The selected family should describe reasonably well all possible states of our knowledge.
- From this viewpoint, it is reasonable to require that:
  - if both fused pieces of knowledge are described by distributions from our family,
  - then the result of fusing these two pieces of knowledge should also belong to our family.

## 10. How to Describe Fusion: A Natural Idea

- In probability theory:
  - if we have two independent events with probabilities  $p_1$  and  $p_2$ ,
  - then the probability that both events will happen is equal to the product of these probabilities.
- Similarly, suppose that we have two independent sources of information, so that.
- Based on information from Source 1, we assign:
  - to each of  $N$  alternatives  $a_1, \dots, a_N$ ,
  - the probabilities  $p_{1,1}, \dots, p_{1,N}$ .
- Based on information from Source 2, we assign:
  - to each of  $M$  alternatives  $b_1, \dots, b_M$ ,
  - the probabilities  $p_{2,1}, \dots, p_{2,M}$ .

## 11. How to Describe Fusion (cont-d)

- Then:
  - the probability that we have alternative  $a_i$  in the first case and alternative  $b_j$  in the second case
  - is equal to the product of the corresponding probabilities  $p_{1,i} \cdot p_{2,j}$ .
- Sometimes, in both cases, we have the exact same set of alternatives.
- Then we need to consider *conditional* probabilities, namely probabilities under the condition that  $i = j$ .
- In general, the conditional probability  $P(A | B)$  of an event  $A$  under the condition  $B$  can be obtained by:
  - dividing the probability  $P(A \& B)$  of  $A \& B$
  - by the probability  $P(B)$  that the condition  $B$  is satisfied.

## 12. How to Describe Fusion (cont-d)

- In our case, this means that after the fusion, the probability of the  $i$ -th alternative is equal to  $p_i = C \cdot p_{1,i} \cdot p_{2,i}$ .
- The coefficient  $C \stackrel{\text{def}}{=} \frac{1}{P(B)}$  can be obtained from the requirement:

– that the resulting probabilities add up to 1,

– i.e., that  $\sum_{i=1}^N p_i = C \cdot \sum_{i=1}^N p_{1,i} \cdot p_{2,i} = 1$ , so that

$$C = \frac{1}{\sum_{i=1}^N p_{1,i} \cdot p_{2,i}}.$$

## 13. How to Describe Fusion (cont-d)

- Similar formulas can be obtained for continuous distributions:
  - if we have two independent sources of information that lead to distributions  $f_1(x)$  and  $f_2(x)$ ,
  - then the fusion of these two pieces of information is a probability distribution  $f(x) = C \cdot f_1(x) \cdot f_2(x)$ .
- Here  $C$  is a normalization constant.
- Similarly, we can define the result of fusing several probability distributions as  $f(x) = C \cdot f_1(x) \cdot \dots \cdot f_k(x)$ .

## 14. Every Piece of Knowledge Can Be Obtained by Fusing “Smaller” Pieces of Information

- Sometimes, knowledge comes in one big step.
- However, more typically, to gain the knowledge, we must acquire it piece by piece.
- Sometimes it comes in two steps, sometimes in three steps, sometimes in four steps, etc.
- So, it is natural to come up with the following definition.
- We say that in a family  $f(x, c)$ , *every piece of knowledge can be obtained by fusing* if
  - for every pdf  $f(x, c)$  from this family and for every integer  $M \geq 2$ ,
  - there exists another pdf  $f(x, c')$  from this family so that fusing  $M$  copies of  $f(x, c')$  leads to  $f(x, c)$ .

## 15. The Family Should Not Depend on the Starting Point and Measuring Unit

- We want to deal with physical quantities, but in reality, we deal with their numerical values.
- These numerical values depend on:
  - what measuring unit we use for measuring the quantity, and
  - what starting point we select for this measurement.
- When we change the measuring unit and/or the starting point, the numerical values change; e.g.:
  - if we change the measuring unit from meters to centimeters,
  - all the numerical values are multiplied by 100, so that, 2 m becomes 200 cm.

## 16. The Family Should Not Depend on the Starting Point and Measuring Unit (cont-d)

- In general:
  - if we change from the original measuring unit to a new one which is  $a$  times smaller,
  - then all the numerical values are multiplied by  $a$ :

$$x \rightarrow a \cdot x.$$

- This transformation is known as *scaling*.
- Similarly, we can change the starting point to the one which is  $b$  units before.
- We can do it for time, temperature, and many other quantities.
- Then  $b$  is added to all the numerical values  $x \rightarrow x + b$ .
- This transformation is known as *shift*.

## 17. The Family Should Not Depend on the Starting Point and Measuring Unit (cont-d)

- If we change both the measuring unit and the starting point, then numerical values change as  $x \rightarrow a \cdot x + b$ .
- These transformations change the pdf  $f(x_1, \dots, x_n)$ :
  - if we apply such transformation  $x_i \rightarrow x'_i \stackrel{\text{def}}{=} a_i \cdot x_i + b_i$  to each of inputs,
  - then in terms of the new numerical values  $x'_1, \dots, x'_n$ , the pdf takes a different form:

$$f'(x'_1, \dots, x'_n) = \frac{1}{\prod_{i=1}^n a_i} \cdot f\left(\frac{x'_1 - b_1}{a_1}, \dots, \frac{x'_n - b_n}{a_n}\right).$$

## 18. The Family Should Not Depend on the Starting Point and Measuring Unit (cont-d)

- We want to come up with a universal family of probability distributions.
- This family should be applicable no matter what measuring units and what starting points we select.
- Thus, it is reasonable to require that our family is invariant w.r.t. the corresponding transformations.
- We say that a family  $F$  is *scale- and shift-invariant* if:
  - every pdf  $f(x, c)$  from this family and for every two tuples  $a$  and  $b$ ,
  - the  $(a, b)$ -re-scaling of the pdf  $f(x, c)$  also belongs to the family  $F$ .

## 19. Main Result

- Let  $F$  be a differentiable family  $f(x, c)$ :
  - which is closed under fusion,
  - for which every piece of knowledge can be obtained by fusing small pieces of information, and
  - which is scale- and shift-invariant.
- Then, there exists an integer  $d \leq m + 1$  such that:
  - every probability density function from this family has the form  $f(x, c) = \exp(P(x_1, \dots, x_n))$ ,
  - where  $P(x_1, \dots, x_n)$  is a polynomial of degree  $\leq d$  with respect to each of its variables.
- This result explains the empirical success of sliced-normal distributions.

## 20. Proof: Part 1

- Let  $F$  be the family that satisfies all the conditions described in the formulation of our result.
- By a *log-function*, we will mean a function of the type  $L(x, c, s) = \ln(f(x, c)) + s$  for some  $c$  and  $s$ .
- Let us denote the class of all log-functions by  $\mathcal{L}$ .
- Let us prove that the class of all log-functions is closed under addition, i.e., that:
  - for every two log-functions
$$L(x, c; , s') \text{ and } L(x, c'', s''),$$
  - their sum is also a log-function.
- Indeed, by definition,  $L(x, c', s') = \ln(f(x, c')) + s'$  and  $L(x, c'', s'') = \ln(f(x, c'')) + s''$ .

## 21. Proof: Part 1 (cont-d)

- Since the family  $F$  is closed under fusion, the result of fusing the corresponding pdfs is also a pdf from  $F$ :

$$C \cdot f(x, c') \cdot f(x, c'') = f(x, c) \text{ for some tuple } c.$$

- By taking logarithms of both sides of this equality, we conclude that

$$\ln(C) + \ln(f(x, c')) + \ln(f(x, c'')) = \ln(f(x, c)).$$

- If we add  $s' + s'' - \ln(C)$  to both sides of the resulting equality, we conclude that

$$\begin{aligned} (\ln(f(x, c')) + s') + (\ln(f(x, c'')) + s'') = \\ \ln(f(x, c)) + (s' + s'' - \ln(C)). \end{aligned}$$

[Sliced-Normal...](#)[But Why?](#)[The Dependence...](#)[The Dependence...](#)[The Class of...](#)[How to Describe...](#)[Every Piece of...](#)[The Family Should...](#)[Main Result](#)[Home Page](#)[Title Page](#)[◀◀](#)[▶▶](#)[◀](#)[▶](#)[Page 23 of 51](#)[Go Back](#)[Full Screen](#)[Close](#)[Quit](#)

## 22. Proof: Part 1 (cont-d)

- So, the sum of the two given log-functions is indeed a log-function:

$$L(x, c', s') + L(x, c'', s'') = L(x, c, s' + s'' - \ln(C)).$$

- The statement is proven.

Quit

## 23. Proof: Part 2

- Let us now prove that:
  - for each log-function  $L(x, c, s)$  and for every integer  $M \geq 2$ ,
  - the function  $M^{-1} \cdot L(x, c, s)$  is also a log-function.
- By definition,  $L(x, c, s) = \ln(f(x, c)) + s$ .
- For the family  $F$ , every piece of knowledge can be obtained by fusing small pieces of information.
- So, the pdf  $f(x, c)$  can be obtained by fusing  $M$  instances of some other pdf  $f(x, c')$ :

$$f(x, c) = C \cdot (f(x, c'))^M.$$

## 24. Proof: Part 2 (cont-d)

- We have  $f(x, c) = C \cdot (f(x, c'))^M$ .
- By taking logarithms of both sides of this equality, we get  $\ln(f(x, c)) = M \cdot \ln(f(x, c')) + \ln(C)$ , thus

$$M^{-1} \cdot \ln(f(x, c)) = \ln(f(x, c')) + M^{-1} \cdot \ln(C).$$

- By adding  $M^{-1} \cdot s$  to both sides, we get

$$M^{-1} \cdot (\ln(f(x, c)) + s) =$$

$$\ln(f(x, c')) + M^{-1} \cdot (\ln(C) + s).$$

- The left-hand side of this formula is exactly

$$M^{-1} \cdot L(x, c, s).$$

- So, it is indeed a log-function.
- The statement is proven.

## 25. Proof: Part 3

- Let us now consider the closure  $\mathcal{C}$  of the set  $\mathcal{L}$  of all log-functions:
  - the closure in the usual topological sense, i.e.,
  - the set of all limit functions with respect to some natural topology on the class of all functions.
- Since the set  $\mathcal{L}$  is closed under addition, its closure  $\mathcal{C}$  is also closed under addition.
- Let us prove that this closure is closed under multiplication by positive numbers.
- In other words, let us prove that:
  - for each function  $f(x) \in \mathcal{C}$  and for every positive real number  $r > 0$ ,
  - the function  $r \cdot f(x)$  also belongs to  $\mathcal{C}$ .

## 26. Proof: Part 3 (cont-d)

- Since  $\mathcal{C}$  is the closure of the set of all log-functions, it is sufficient to prove that:
  - for each log-function  $L(x, c, s)$  and for every positive real number  $r > 0$ ,
  - the function  $r \cdot L(x, c, s)$  is a limit of log-functions.
- Indeed, for every possible accuracy  $\varepsilon > 0$ :
  - we can approximate, with this accuracy,
  - the real number  $r$  by a rational number  $\frac{N}{M}$ .
- By Part 2 of this proof, the function  $M^{-1} \cdot L(x, c, s)$  is also a log-function.

## 27. Proof: Part 3 (cont-d)

- Now, by Part 1 of this proof:
  - the function  $\frac{N}{M} \cdot L(x, c, s)$  is also a log-function,
  - as the sum of  $N$  log-functions  $M^{-1} \cdot L(x, c, s)$ .
- When  $\frac{N}{M}$  tends to  $r$ , the corresponding function  $\frac{N}{M} \cdot L(x, c, s)$  tends to  $r \cdot L(x, c, s)$ .
- Thus, the function  $r \cdot L(x, c, s)$  is indeed a limit of log-functions.
- The statement is proven.

## 28. Proof: Part 4

- By combining Parts 1 and 3, we conclude that:
  - for every finite set of functions  $C_1(x), \dots, C_k(x)$  from the set  $\mathcal{C}$ , and
  - for every tuple of positive numbers  $r_1, \dots, r_k$ ,
  - the linear combination  $r_1 \cdot C_1(x) + \dots + r_k \cdot C_k(x)$  also belongs to  $\mathcal{C}$ .
- Let us prove that the set  $\mathcal{C}$  cannot contain more than  $m + 1$  linearly independent functions; indeed:
  - if this was the case, and we would have more than  $m + 1$  linearly independent functions,
  - then we would have at least  $m + 2$  of them  $C_1(x), \dots, C_{m+2}(x)$  in the class  $\mathcal{C}$ .
- Then, the class  $\mathcal{C}$  will contain a  $(m + 2)$ -parametric family of functions  $r_1 \cdot C_1(x) + \dots + r_{m+2} \cdot C_{m+2}(x)$ .

## 29. Proof: Part 4 (cont-d)

- However, the class  $\mathcal{C}$  is the closure of the class  $\mathcal{L}$  of functions of the type  $\ln(f(x, c)) + s$ .
- This class depends on  $m + 1$  parameters:
  - we have  $m$  parameters  $c_1, \dots, c_m$  and
  - we have an additional parameter  $s$ .
- So, the closure of this set is also of dimension  $m + 1$  (or less).
- Thus, cannot contain more-dimensional subfamilies.
- The statement is proven.

## 30. Proof: Part 5

- Let us denote by  $\mathcal{S}$  the class of all linear combinations of functions from the class  $\mathcal{C}$ .
- Clearly,  $\mathcal{C} \subseteq \mathcal{S}$ .
- Due to Part 4, the dimension  $d$  of the linear space  $\mathcal{S}$  cannot exceed  $m + 1$ ; so:

- if we pick any basis  $e_1(x), \dots, e_d(x)$  in this class,
- then each function  $f(x) \in \mathcal{S}$  can be represented as

$$f(x) = C_1 \cdot e_1(x) + \dots + C_d \cdot e_d(x).$$

- We can pick the basis from the set  $\mathcal{C}$ ; moreover:
  - since the closure does not change the dimension,
  - we can pick this basis from the original class  $\mathcal{L}$  of log-functions.

## 31. Proof: Part 5 (cont-d)

- All the pdf functions from the family  $F$  are, by our assumption, differentiable.
- Thus, every log-function is also differentiable.
- Hence, we can choose the basis of differentiable functions.

## 32. Proof: Part 6

- Let us prove that the class  $\mathcal{L}$  is closed under arbitrary re-scalings, i.e.:
  - if a function  $f(x_1, \dots, x_n)$  is in this class,
  - then for each tuple  $a = (a_1, \dots, a_n)$  of positive numbers and for each tuple  $b = (b_1, \dots, b_n)$  of real numbers, the function  $f(a \cdot x_1 + b_1, \dots, a_n \cdot x_n + b_n)$  also belongs to the class  $\mathcal{L}$ .
- This follows:
  - from the requirement that the family  $F$  is scale- and shift-invariant,
  - if we take logarithms of both sides and add appropriate constants to both sides.
- From this, we can conclude that the closure class  $\mathcal{C}$  is also invariant with respect to arbitrary re-scalings.

### 33. Proof: Part 6 (cont-d)

- So, the class  $\mathcal{S}$  of all linear combinations of functions from  $\mathcal{C}$  is also thus invariant.
- Let us first study the consequences of shift-invariance of the class  $\mathcal{S}$  with respect to the first variable.
- This shift-invariance implies, in particular, that:
  - for each basis function  $e_i(x_1, x_2, \dots, x_n)$ ,
  - the result of its shift  $e_i(x_1 + b_1, x_2, \dots, x_n)$  is also a function from  $\mathcal{S}$ , i.e., for some  $C_{ij}$ :

$$e_i(x_1 + b_1, x_2, \dots, x_n) = \sum_{j=1}^d C_{ij}(b_1) \cdot e_j(x_1, x_2, \dots, x_n).$$

- For a while, let us fix the values  $x_2, \dots, x_n$  and only consider the dependence on  $x_1$ .

## 34. Proof: Part 6 (cont-d)

- In other words, let us consider auxiliary functions

$$E_i(x_1) \stackrel{\text{def}}{=} e_i(x_1, x_2, \dots, x_n).$$

- For these auxiliary functions, the above formula takes the form

$$E_1(x_1 + b_1) = C_{11}(b_1) \cdot E_1(x_1) + \dots + C_{1d}(b_1) \cdot E_d(x_1);$$

...

$$E_d(x_1 + b_1) = C_{d1}(b_1) \cdot E_1(x_1) + \dots + C_{dd}(b_1) \cdot E_d(x_1).$$

- Here, all the functions  $E_1(x_1) \dots, E_d(x_1)$  are differentiable – since:
  - they come by fixing some values from the basis functions  $e_i(x_1, \dots, x_n)$ , and
  - the basis functions are differentiable.

## 35. Proof: Part 6 (cont-d)

- Let us prove that the dependencies  $C_{ij}(b_1)$  are also differentiable.
- Indeed, for each  $i$ , let us pick  $d$  different values  $x_{1,1}, \dots, x_{1,d}$  of  $x_1$ .
- Then we get the following  $d$  linear equations for  $d$  unknowns  $C_{i1}(b_1), \dots, C_{id}(b_1)$ :

$$E_i(x_{1,1} + b_1) = C_{i1}(b_1) \cdot E_1(x_{1,1}) + \dots + C_{id}(b_1) \cdot E_d(x_{1,1});$$

...

$$E_i(x_{1,d} + b_1) = C_{i1}(b_1) \cdot E_1(x_{1,d}) + \dots + C_{id}(b_1) \cdot E_d(x_{1,d}).$$

- Each element  $C_{ij}(b_1)$  of the solution to a system of linear equations can be described, by the Cramer rule:
  - as the ratio of two determinants, i.e.,
  - as a smooth function of all the coefficients.

## 36. Proof: Part 6 (cont-d)

- The coefficients  $E_i(x_{1,k} + b_1)$  smoothly depend on  $b_1$ .
- So, we conclude that the solutions  $C_{ij}(b_1)$  are also differentiable functions of  $b_1$ .
- Since all the functions  $E_i(x_1)$  and  $C_{ij}(b_1)$  are differentiable, we can:

- differentiate both sides of all equalities describing  $E_i(x_1 + b_1)$  with respect to  $b_1$ ,
- and take  $b_1 = 0$ .

- Then, we get the following system of equations:

$$E_1'(x_1) = c_{11} \cdot E_1(x_1) + \dots + c_{1d} \cdot E_d(x_1);$$

...

$$E_d'(x_1) = c_{d1} \cdot E_1(x_1) + \dots + c_{dd} \cdot E_d(x_1).$$

- Here,  $E_i'(x_1)$  denotes the derivative, and  $c_{ij} \stackrel{\text{def}}{=} C'_{ij}(0)$ .

## 37. Proof: Part 6 (cont-d)

- In other words:
  - for the functions  $E_1(x), \dots, E_d(x)$ ,
  - we get a system of linear differential equations with constant coefficients.
- It is known that a general solution to such system of equations is a linear combination
  - of functions of the type  $x_1^k \cdot \exp((p + i \cdot q) \cdot x_1)$ , i.e.,
  - functions of the type  $x_1^k \cdot \exp(p \cdot x_1) \cdot \cos(q \cdot x_1)$  and  $x_1^k \cdot \exp(p \cdot x_1) \cdot \sin(q \cdot x_1)$ .

## 38. Proof: Part 6 (cont-d)

- Here:
  - the values  $p + i \cdot q$  are eigenvalues of the matrix  $c_{ij}$ ,
  - and  $k$  is a non-negative integer corresponding to duplicate eigenvalues.
- For a  $d \times d$  matrix, the multiplicity of an eigenvalue cannot exceed  $d$ , so  $k \leq d$ .

## 39. Proof: Part 7

- Let us now study the consequences of *scale*-invariance of the class  $\mathcal{S}$  with respect to the first variable.
- This scale-invariance implies, in particular, that:
  - for each basis function  $e_i(x_1, x_2, \dots, x_n)$ ,
  - the result of its re-scaling  $e_i(a_1 \cdot x_1, x_2, \dots, x_n)$  is also a function from  $\mathcal{S}$ , i.e., for some  $D_{ij}$ :

$$e_i(a_1 \cdot x_1, x_2, \dots, x_n) = \sum_{j=1}^d D_{ij}(a_1) \cdot e_j(x_1, x_2, \dots, x_n).$$

- Thus:

$$E_1(a_1 \cdot x_1) = D_{11}(a_1) \cdot E_1(x_1) + \dots + D_{1d}(a_1) \cdot E_d(x_1);$$

...

$$E_d(a_1 \cdot x_1) = D_{d1}(a_1) \cdot E_1(x_1) + \dots + D_{dd}(a_1) \cdot E_d(x_1).$$

## 40. Proof: Part 7 (cont-d)

- Similarly to Part 6, we can prove that the dependencies  $D_{ij}(a_1)$  are also differentiable.
- By differentiating both sides of the above equations with respect to  $a_1$  and taking  $a_1 = 1$ , we conclude that

$$x_1 \cdot E'_1(x_1) = d_{11} \cdot E_1(x_1) + \dots + d_{1d} \cdot E_d(x_1);$$

...

$$x_1 \cdot E'_d(x_1) = d_{d1} \cdot E_1(x_1) + \dots + d_{dd} \cdot E_d(x_1).$$

- In each equation, the left-hand side  $x_1 \cdot \frac{dE_i}{dx_1}$  can be reformulated as  $\frac{dE_i}{dx_1/x_1} = \frac{dE_i}{d(\ln(x_1))}$ .

## 41. Proof: Part 7 (cont-d)

- Thus, for  $X_1 \stackrel{\text{def}}{=} \ln(x_1)$ , we get the system of linear differential equations with constant coefficients:

$$\frac{dE_1}{dX_1} = d_{11} \cdot E_1(X_1) + \dots + d_{1d} \cdot E_d(X_1);$$

...

$$\frac{dE_d}{dX_1} = d_{d1} \cdot E_1(X_1) + \dots + d_{dd} \cdot E_d(X_1).$$

- We already know that a general solution to this equation is a linear combination of functions

$$X_1^k \cdot \exp(p \cdot X_1) \cdot \cos(q \cdot X_1) \text{ and} \\ x_1^k \cdot \exp(p \cdot X_1) \cdot \sin(q \cdot X_1).$$

## 42. Proof: Part 7 (cont-d)

- Let us substitute  $X_1 = \ln(x_1)$  into these formulas and take into account that

$$\exp(p \cdot \ln(x_1)) = (\exp(\ln(x_1)))^p = x_1^p.$$

- We conclude that a general solution is a linear combination of functions

$$(\ln(x_1))^k \cdot x_1^p \cdot \cos(q \cdot \ln(x_1)) \text{ and} \\ (\ln(x_1))^k \cdot x_1^p \cdot \sin(q \cdot \ln(x_1)).$$

## 43. Proof: Part 8

- From Parts 7 and 8, we get two different expressions for the functions  $E_i(x_1)$ .
- By comparing these expressions, one can easily see that:
  - the only functions that can be described in both forms
  - are functions of the form  $x^k$  for some non-negative integer  $k \leq d$
  - or their linear combinations.
- So, each function  $E_i(x_1)$  is a linear combination of such functions – i.e., a polynomial.

## 44. Proof: Part 8 (cont-d)

- We have shown that for each combination of values of  $x_2, \dots, x_n$ :
  - the dependence of each function  $e_i(x_1, x_2, \dots, x_n)$  on  $x_1$
  - can be described by a polynomial of degree  $\leq d$ .
- Similarly, we can prove that:
  - for each combination of values  $x_1, x_3, \dots, x_n$ ,
  - the dependence on  $x_2$  is also described by a polynomial.
- Let us combine these two conclusions and prove that for all possible values of  $x_3, \dots, x_n$ :
  - the dependence of  $e_i(x_1, x_2, x_3, \dots, x_n)$  on  $x_1$  and on  $x_2$
  - can be described by a polynomial of two variables.

## 45. Proof: Part 8 (cont-d)

- Indeed, let us denote  $T(x_1, x_2) \stackrel{\text{def}}{=} e_i(x_1, x_2, x_3, \dots, x_n)$ .
- We know that:
  - for each  $x_2$ , this expression is a polynomial in  $x_1$ , and
  - for each  $x_1$ , this expression is a polynomial in  $x_2$ .
- Let us prove that  $T(x_1, x_2)$  is a polynomial of two variables.
- Indeed:
  - the fact that the dependence of  $e_i$  on  $x_1$  can be described by a polynomial of order  $\leq d$
  - can be rewritten, in terms of  $T(x_1, x_2)$ , as:
$$T(x_1, x_2) = a_0(x_2) + a_1(x_2) \cdot x_1 + \dots + a_d(x_2) \cdot x_1^d.$$

## 46. Proof: Part 8 (cont-d)

- In writing this expression, we took into account that, in general:
  - for different values of  $x_2$ ,
  - the coefficients  $a_0, \dots, a_d$  of this polynomial may be different.
- Let us substitute  $d_1$  different values  $x_{1,0}, \dots, x_{1,d}$  of  $x_1$  into this formula.
- As a result, we have  $d+1$  linear equations for  $d+1$  unknowns  $a_0(x_2), \dots, a_d(x_2)$ , with constant coefficients:

$$T(x_{1,0}, x_2) = a_0(x_2) + a_1(x_2) \cdot x_{1,0} + \dots + a_d(x_2) \cdot x_{1,0}^d;$$

...

$$T(x_{1,d}, x_2) = a_0(x_2) + a_1(x_2) \cdot x_{1,d} + \dots + a_d(x_2) \cdot x_{1,d}^d.$$

## 47. Proof: Part 8 (cont-d)

- In general:
  - each component in a solution to a system of linear equations
  - is a linear combination of the right-hand sides.
- The right-hand sides  $T(x_{1,i}, x_2)$  are polynomials of  $x_2$ .
- Thus, each coefficient  $a_i(x_2)$  is a linear combination of polynomials – thus, a polynomial itself.
- All the expressions  $a_i(x_2)$  are polynomials.
- Thus, the whole above expression for  $T(x_1, x_2)$  becomes a polynomial in two variables  $x_1$  and  $x_2$ .

## 48. Proof: Part 8 (cont-d)

- By adding variables one by one, we can prove that the dependence of each basis function  $e_i(x_1, \dots, x_n)$ :
  - on  $x_1, x_2$ , and  $x_3$  is a polynomial,
  - ...
  - on all  $n$  variables  $x_1, \dots, x_n$  is a polynomial.
- Thus, each element of  $\mathcal{S}$  – which is a linear combination of the basis functions – is also a polynomial.
- For each tuple  $c$ , the function  $\ln(f(x, c))$  belongs to the class  $\mathcal{L} \subseteq \mathcal{S}$  and is, thus, also a polynomial.
- So, indeed, each pdf  $f(x, c)$  from the family  $F$  has the form  $\exp(P(x_1, \dots, x_n))$  for some polynomial

$$P(x_1, \dots, x_n).$$

- Our main result is proven.
