# 1. Many Practical Situations Eventually Reach Equilibrium; Examples

- In *economics*,
  - a situation changes;
  - prices start changing (often fluctuating);
  - eventually, prices reach an equilibrium between supply and demand.

In *transportation*,

- a new road is built;
- some traffic moves to this road to avoid congestion on the other roads;
- this move causes congestion on the new road;
- as a result, some drivers go back to their previous routes;
- etc.

## 2. Specific Challenges of Transportation Applications

- *Intuitively*: a road expansion (e.g., the opening of a new road) should always improve the traffic conditions.
- *In reality*: a new road can actually worsen traffic congestion:
  - too many cars move to a new road;
  - as a result, the new road becomes even more congested than the old roads initially were;
  - so the traffic situation will actually decrease.
- *Conclusion*: a possible negative effect of a new road on congestion.
- This negative effect is known as a paradox of transportation science.
- Due to this paradox, we need a detailed analysis in the planning of the new road.

### 3. It Is Often Desirable to Predict the Corresponding Equilibrium

- For the purposes of the long-term planning, it is desirable to find the corresponding equilibrium.
- *Economic example:* how, in the long run, oil prices will change if we start exploring new oil fields in Alaska?
- *Transportation example:* to what extent the introduction of a new road will relieve the traffic congestion?
- *General objective:* solve the practically important problem of predicting the equilibrium.
- *First step:* describe the equilibrium prediction problem in precise terms.

## 4. Finding an Equilibrium as a Mathematical Problem

- *Non-equilibrium states*: economic example:
  - *situation*: oil price is too high;
  - *result*: profitable to explore difficult-to-extract oil fields;
  - *new result*: the supply of oil increases, and prices drop.
- *Non-equilibrium states*: transportation example:
  - *situation*: too many cars move to a new road;
  - *results*: the new road becomes congested;
  - *new result*: drivers abandon the new road.
- *General description*: given a current state  $x$ , we can determine the state  $f(x)$  at the next moment of time.
- *Equilibrium*: a state that does not change  $f(x) = x$  (i.e., a fixed point).

## 5. Fixed Points in Transportation Engineering

- *Traffic demand*: # of drivers  $d_{ij}$  who need to go from zone  $i$  to zone  $j$  – *origin-to-destination* (O-D) matrix.
- *Capacity* of a road link – the number  $c$  of cars per hour which can pass through this link.
- *Travel time along a link*:  $t = t^f \cdot \left[ 1 + a \cdot \left( \frac{v}{c} \right)^\beta \right]$ , where:
  - $t^f = L/s$  is a *free-flow* time ( $s$  is the speed limit),
  - $a \approx 0.15$  and  $\beta \approx 4$  are empirical constants.
- *Equilibrium*: when
  - the travel time along all used alternative routes is exactly the same, and
  - the travel times along other un-used routes is higher.
- *Algorithms*: there exist efficient algorithms for finding the equilibrium.

## 6. Fixed Points in Transportation Engineering: Dynamic Case

- *We need to know:* O-D values  $d_{ij}(t)$  for all  $t$ .
- *Problem:* if we build a new road, the values  $d_{ij}(t)$  may change.
- *Example:*
  - the driver needs to be at work at 8:00 am;
  - the travel time is 30 minutes;
  - a new freeway decreases the expected travel time to 15 minutes.
- *Original decision:* leave home at 7:30 am.
- *New decision:* leave home at 7:45 am.
- *Conclusion:*  $d_{ij}(7:30) \downarrow$  while  $d_{ij}(7:45) \uparrow$ .
- *Important:* take this choice of departure time into account.

## 7. How Drivers Select Departure Time

- *Logit model*: the probability  $P_i$  that a driver will choose the  $i$ -th time interval is proportional to  $\exp(u_i)$ :

$$P_i = \frac{\exp(u_i)}{\exp(u_1) + \dots + \exp(u_n)}.$$

- *Describing preferences*: empirical utility formula

$$u_i = -0.1051 \cdot E(T) - 0.0931 \cdot E(SDE) - 0.1299 \cdot E(SDL) - 1.3466 \cdot P_L - 0.3463 \cdot \frac{S}{E(T)},$$

where  $E(X)$  means expected value,

- $T$  is the travel time  $T$ ,
- $SDE$  is the wait time when arriving early,
- $SDL$  is the delay when arriving late,
- $P_L$  is the probability of arriving late, and
- $S$  is the variance of the travel time.

## 8. Resulting Algorithm

- *Start:* with the 1st approximation O-D matrices  $d_{ij}(t)$ .
- *Iteration:*
  - Based on the values  $d_{ij}(t)$ , we find travel times at different time of the day  $t$ .
  - Based on the travel times, we estimate utilities  $u_i$  of different start times.
  - From  $u_i$ , we compute the probabilities  $P_i$  of selecting different start times.
  - Multiplying these probabilities by the number of drives who need to get from  $i$  to  $j$ , we get new O-D matrices  $d_{ij}(t)$ .
  - Repeat until converges.
- *General case:*  $x_{k+1} = f(x_k)$  (Picard iterations).

## 9. Situations when Picard's Iterations do not Converge: Economics

- *Main idea:* panicky fluctuations prevent convergence.
- *Example: reminder*
  - the price of oil is high;
  - it becomes profitable for companies to explore new oil fields;
  - as a result, the supply of oil will drastically increase, and the price of oil will go down.
- *Comment:* this is all done in a unplanned way.
- *Result:* supply exceeds demand.
- *Fact:* such fluctuations have happened in economics in the past.
- *Historical fact:* fluctuations have led to deep economic crises.

## 10. Situations when Picard's Iterations do not Converge: Transportation

- *Toy example illustrating a problem:*
  - now: no congestion, all start at 7:30, work at 8 am;
  - $M_1$ : full O-D matrix for 7:30 am, 0 for 7:15 am;
  - based on this  $M_1$ , we get huge delays;
  - $M_2$ : everyone leaves for work early at 7:15 am;
  - at 7:30, roads are freer, so in  $M_3$ , all start at 7:30;
  - no convergence:  $M_1 = M_3 = \dots \neq M_2 = M_4 \dots$

## 11. A More Realistic Approach

- *Above idea*: drivers make decisions based only on *previous* day traffic.
- *More accurate idea*: drivers make decisions based on the *average* traffic over a few past days.
- *Resulting process*:
  - start with the 1st approximation O-D matrices  $M_1$ ;
  - for  $i = 2, 3, \dots$ :
    - \* compute the average  $E_i = \frac{M_1 + \dots + M_i}{i}$ ,
    - \* find traffic times based on  $E_i$ ;
    - \* use these traffic times to compute a new O-D matrix  $M_{i+1} = F(E_i)$ ;
    - \* repeat until converges.
- *Process converges*: on toy examples, on El Paso network, etc.

## 12. Algorithm Simplified

- *Main idea:* once we know the previous average  $E_i$ , we can compute

$$E_{i+1} = \frac{(M_1 + \dots + M_i) + M_{i+1}}{i + 1} = \frac{i \cdot E_i + M_{i+1}}{i + 1} = E_i \cdot \left(1 - \frac{1}{i + 1}\right) + M_{i+1} \cdot \frac{1}{i + 1}.$$

- *We know:* that  $M_{i+1} = F(E_i)$ .
- *Resulting algorithm:*
  - start with the 1st approximation O-D matrices

$$E_1 = M_1;$$

- compute  $E_{i+1} = E_i \cdot \left(1 - \frac{1}{i + 1}\right) + F(E_i) \cdot \frac{1}{i + 1}$ ;
- repeat until converges.

## 13. Towards an Optimal Algorithm for Computing Fixed Points

- *Idea*: when iterations  $x_{k+1} = f(x_k)$  do not converge,  
$$x_{k+1} = x_k + \alpha \cdot (f(x_k) - x_k) = (1 - \alpha_k) \cdot x_k + \alpha_k \cdot f(x_k).$$

- *Question*: which choice of  $\alpha_k$  is best?

- *Idea*: this is a discrete approximation to a continuous-time system  $\frac{dx}{dt} = \alpha(t) \cdot (f(x) - x).$

- *Scale invariance*: the system should not change if we use a different discretization, i.e., re-scale  $t$  to  $t' = t/\lambda$ :

$$\frac{dx}{dt'} = (\lambda \cdot \alpha(\lambda \cdot t')) \cdot (f(x) - x).$$

- *Conclusion*:  $\lambda \cdot \alpha(\lambda \cdot t') = a(t')$ , so for  $\lambda = 1/t'$ , we get  $\alpha(t') = \frac{c}{t'}$  for some  $c$ .
- *Fact*: this is exactly what we used:  $\alpha_k = 1/k$ .

## 15. Logit Discrete Choice Model: A New Justification

- *Reasonable assumption*: if we add same incentive to all routes, probabilities will not change.
- *For 2 routes*:  $P_1 = F(\Delta V)$ , where  $\Delta V \stackrel{\text{def}}{=} V_1 - V_2$ .
- *Bayes theorem*:

$$P(H_i | E) = \frac{P(E | H_i) \cdot P_0(H_i)}{P(E | H_1) \cdot P_0(H_1) + \dots + P(E | H_n) \cdot P_0(H_n)}.$$

- *Idea*: if we add an incentive  $v_0$  to one of the routes, this changes the probability of selecting this route:

$$F(\Delta V + v_0) = \frac{A(v_0) \cdot F(\Delta V)}{A(v_0) \cdot F(\Delta V) + B(v_0) \cdot (1 - F(\Delta V))}.$$

- *Conclusion*:  $F(\Delta V) = \frac{1}{1 + e^{-\beta \cdot \Delta V}}$ , so

$$p_1 = F(V_1 - V_2) = \frac{e^{\beta \cdot V_1}}{e^{\beta \cdot V_1} + e^{\beta \cdot V_2}}.$$

## 16. Taking Uncertainty into Account

- *Deterministic model*:  $t = t^f \cdot \left[ 1 + a \cdot \left( \frac{v}{c} \right)^\beta \right]$ .
- *Traffic assignment*: a driver minimizes the travel time  $t = t_1 + \dots + t_n$ .
- *In practice*: travel times vary.
- *Decision theory*: maximize expected utility  $E[u]$ .
- *How utility depends on travel time*:  $u(t) = -U(t)$ , where  $U(t) = \exp(\alpha \cdot t)$ .
- *Conclusion*: the driver minimizes
$$E[U(t)] = E[\exp(\alpha \cdot t)] = E[\exp(\alpha \cdot (t_1 + \dots + t_n))] = E[\exp(\alpha \cdot t_1) \cdot \dots \cdot \exp(\alpha \cdot t_n)].$$
- Deviations on different links are independent, so
$$E[U(t)] = E[\exp(\alpha \cdot t_1)] \cdot \dots \cdot E[\exp(\alpha \cdot t_n)].$$

## 17. Taking Uncertainty into Account (cont-d)

- Minimizing  $E[U(t)] = E[\exp(\alpha \cdot t_1)] \cdot \dots \cdot E[\exp(\alpha \cdot t_n)]$   
 $\Leftrightarrow$  minimizing  $\sum_{i=1}^n \tilde{t}_i$ , where  $\tilde{t}_i \stackrel{\text{def}}{=} \ln(E[\exp(\alpha \cdot t_i)])$ .

- $\tilde{t}$  depends on  $t^f$  and  $r \stackrel{\text{def}}{=} \frac{\tilde{t} - t^f}{t}$ :  $\tilde{t} = F(t^f, r)$ .

- If we divide a link into sublinks, we conclude that  $F(t_1^f + t_2^f, r) = F(t_1^f, r) + F(t_2^f, r)$ , hence  $\tilde{t} = t^f \cdot k(r)$ .

- For no-congestion case  $r = 0$ , we have  $\tilde{t} = t^f$ , so  $k(0) = 1$  and  $k(r) = 1 + a_0 \cdot r + a_2 \cdot r_2 + \dots$

- *Empirical analysis*:  $a_1 \approx 1.4$ ,  $b \approx 0$ , so

$$\tilde{t} = t^f \cdot \left[ 1 + a \cdot a_1 \cdot \left( \frac{v}{c} \right)^\beta \right].$$

- *Solution*: use the standard travel time formula with  $a \cdot a_1 \approx 0.21$  instead of  $a \approx 0.14$ .

## 18. Exponential Disutility Functions in Transportation Modeling: Justification

- *Situation:*

- *Reasonable assumption:* the driver starting at C will choose the same road as the driver starting at A.
- *Formally:* if  $E[u(t_1)] < E[u(t_2)]$  then
$$E[u(t_1 + t_0)] < E[u(t_2 + t_0)].$$
- *Result:*  $u(t) = t$ ,  $u(t) = \exp(c \cdot t)$ , or
$$u(t) = -\exp(-c \cdot t).$$
- *Fact:* this is exactly the empirically justified formula used in transportation.
