Cracks and Potholes Natural Symmetries Scaling-to-Scaling (sc-sc) Shift-to-Scaling (sh-sc) Scaling-to-Shift (sc-sh) Shift-to-Shift (sh-sh) What Are Possible ... First Idea So What Do We Do? Home Page **>>** Page 1 of 28 Go Back Full Screen Close Quit

- When a road is built, it is almost perfect it has only miniature cracks and potholes.
- However, as the road is used, cracks and potholes appear and start growing.
- The amount of cracks is gauged the overall length C of longitudal cracks outside the wheel path.
- ullet The amount of potholes is usually gauged by the total area P of potholes.
- As the road is used, the quality of the pavement deteriorates, and the values C and P grow.
- This growth starts at some small values corresponding to the newly built road age t=0.

## 2. Cracks and Potholes (cont-d)

- It continues growing until they reach the maximum the undesirable bad state.
- In this state, the whole road is covered by cracks and potholes.
- The empirical formulas for this growth are:

$$C = a_C \cdot \exp(-b_C \cdot \exp(-c_C \cdot t)); \quad P = a_P \cdot \exp(-b_P \cdot \exp(-c_P \cdot t)).$$

• In this talk, we use natural symmetry ideas to provide a theoretical explanation for these empirical formulas. #### 3. Natural Transformations

- In science and engineering, we are interested in the values of different physical quantities.
- We describe these quantities in numerical form.
- However, the numerical values of the corresponding quantities depend on the measuring unit.
- For some quantities such as temperature or time, the values also depend on the starting point.
- If we change the measuring unit for length from meters to centimeters, then all numerical values are  $\times$  by 100.
- For example, 2 m becomes  $2 \cdot 100 = 200$  cm.

## 4. Natural Transformations (cont-d)

- In general:
  - if we replace the original measuring unit with a new unit which is  $\lambda$  times smaller,
  - all numerical values are multiplied by  $\lambda$ :

$$x \to X = \lambda \cdot x$$
.

- This numerical transformation is known as *scaling*.
- Similarly, we can start measuring time:
  - not from our year 0,
  - but as the French Revolution suggested with the year 1789 when the revolution started.
- Then from all year values, we should subtract 1789.

Natural Symmetries Scaling-to-Scaling (sc-sc) Shift-to-Scaling (sh-sc) Scaling-to-Shift (sc-sh) Shift-to-Shift (sh-sh) What Are Possible . . . First Idea So What Do We Do? Home Page Title Page **>>** Page 5 of 28 Go Back Full Screen Close Quit

## 5. Natural Transformations (cont-d)

- In general:
  - if we replace the original starting point with the one which is  $x_0$  units before,
  - then we add  $x_0$  to all numerical values:

$$x \to X = x + x_0$$
.

• This numerical transformation is known as *shift*.

## 6. Natural Symmetries

- For most physical quantities, there is no fixed measuring unit and sometimes no fixed starting point.
- It is therefore reasonable to require that:
  - the dependencies y = f(x) between physical quantities
  - also not depend on the choice of the measuring unit
  - (and possibly on the choice of the starting point).
- In physics, such invariance is called *symmetry*.

## 7. Natural Symmetries (cont-d)

- Of course:
  - if we just change the unit and/or starting point for x,
  - to keep the same formula true in the new units, we may need to appropriately change y.
- For example, to preserve the formula  $d = v \cdot t$  that the path is the product of speed and time:
  - when we change the unit for time,
  - we need to appropriately change the unit for speed.
- With this is mind, let us describe possible invariant dependencies.

# 3. Scaling-to-Scaling (sc-sc)

- Let us first consider the case when the dependence remains the same after we apply scaling to x and y.
- In precise terms, we assume that for every  $\lambda > 0$ , there exists a value  $\mu(\lambda)$  (depending on  $\lambda$ ) such that:
  - if y = f(x),
  - then Y = f(X), where  $X = \lambda \cdot x$  and  $Y = \mu(\lambda) \cdot y$ .
- If we plug in the expressions for Y in terms of y and X in terms of x into Y = f(X), we get  $f(\lambda \cdot x) = \mu(\lambda) \cdot y$ .
- Here, y = f(x), so  $f(\lambda \cdot x) = \mu(\lambda) \cdot f(x)$ .
- It is known that every measurable dependence f(x) with this property has the form  $f(x) = A \cdot x^a$ .

#### 9. Comment

- The general proof is somewhat complicated.
- However, most physical dependencies are differentiable.
- For differentiable f(x), this is easy to prove.
- Indeed, if f(x) is differentiable, then the function  $\mu(\lambda) = \frac{f(\lambda \cdot x)}{f(x)}$  is differentiable too.
- Thus, we can differentiate both sides of the equation  $f(\lambda \cdot x) = \mu(\lambda) \cdot f(x)$  with respect to  $\lambda$ .
- As a result, we get  $x \cdot f'(\lambda \cdot x) = \mu'(\lambda) \cdot f(x)$ .
- In particular, for  $\lambda = 1$ , we get  $x \cdot \frac{df}{dx} = a \cdot f$ , where

$$a \stackrel{\text{def}}{=} \mu'(1).$$

## 10. Comment (cont-d)

- We can separate x and f if we multiply both sides of the equality by  $\frac{dx}{x \cdot f} : \frac{df}{f} = a \cdot \frac{dx}{x}$ .
- Integrating both sides, we get  $\ln(f) = a \cdot \ln(x) + C$ , where C is the integration constant.
- Applying the function  $\exp(z)$  of both sides, we get the desired expression  $f(x) = A \cdot x^a$ , with  $A = \exp(C)$ .

Natural Symmetries Scaling-to-Scaling (sc-sc) Shift-to-Scaling (sh-sc) Scaling-to-Shift (sc-sh) Shift-to-Shift (sh-sh) What Are Possible . . . First Idea So What Do We Do? Home Page Title Page **>>** Page 11 of 28 Go Back Full Screen Close Quit

#### Shift-to-Scaling (sh-sc) 11.

- Let us consider the case when the dependence remains the same after we apply shift to x and scaling to y.
- In this case, for every  $x_0$ , there exists a value  $\mu(x_0)$ (depending on  $x_0$ ) such that:
  - if y = f(x),
  - then we have Y = f(X), where  $X = x + x_0$  and

$$Y = \mu(x_0) \cdot y.$$

• If we plug in the expressions for Y in terms of y and X in terms of x into Y = f(X), we get

$$f(x+x_0) = \mu(x_0) \cdot y.$$

- Here, y = f(x), so  $f(x + x_0) = \mu(x_0) \cdot f(x)$ .
- It is known that every measurable dependence f(x)with this property has the form  $f(x) = A \cdot \exp(a \cdot x)$ .

## 13. Scaling-to-Shift (sc-sh)

- Let us now consider the case when the dependence remains the same after we scale x and shift y.
- In precise terms, we assume that for every  $\lambda > 0$ , there exists a value  $y_0(\lambda)$  (depending on  $\lambda$ ) such that:
  - if y = f(x),
  - then Y = f(X), where  $X = \lambda \cdot x$  and  $Y = y + y_0(\lambda)$ .
- If we plug in the expressions for Y in terms of y and X in terms of x Y = f(X), we get  $f(\lambda \cdot x) = y + y_0(\lambda)$ .
- Here, y = f(x), so  $f(\lambda \cdot x) = f(x) + y_0(\lambda)$ .
- It is known that every measurable dependence f(x) with this property has the form  $f(x) = a \cdot \ln(x) + C$ .

#### 16. Comment

- If f(x) is differentiable, then the function  $y_0(x_0) = f(x+x_0) f(x)$  is differentiable too.
- Thus, we can differentiate both sides of the equation  $f(x + x_0) = f(x) + y_0(x_0)$  with respect to  $x_0$ .
- As a result, we get  $f'(x + x_0) = y'_0(x_0)$ .
- In particular, for  $x_0 = 0$ , we get f'(x) = a, where

$$a \stackrel{\text{def}}{=} y_0'(0).$$

• Integrating, we get  $f(x) = a \cdot x + C$ , where C is the integration constant.

## 17. What We Want: A Brief Reminder

- We want to find the dependence of the quantity q (crack or pothole amount) on time t; we know:
  - that the for t = 0, the value q(t) is small positive,
  - that the value q(t) increases with time, and
  - that the value q(t) tends to some large constant value when t increases.

Natural Symmetries Scaling-to-Scaling (sc-sc) Shift-to-Scaling (sh-sc) Scaling-to-Shift (sc-sh) Shift-to-Shift (sh-sh) What Are Possible . . . First Idea So What Do We Do? Home Page Title Page **>>** Page 18 of 28 Go Back Full Screen Close Quit

## 18. What Are Possible Symmetries Here?

- For crack amount C and for pothole amount P, there is an absolute starting point: 0.
- Then, we have no cracks and no potholes.
- However, it makes sense to use different units of length and different units of area.
- So scaling makes perfect sense.
- For time, as we have mentioned, both shift and scaling make sense.

Natural Symmetries Scaling-to-Scaling (sc-sc) Shift-to-Scaling (sh-sc) Scaling-to-Shift (sc-sh) Shift-to-Shift (sh-sh) What Are Possible . . . First Idea So What Do We Do? Home Page Title Page **>>** Page 19 of 28 Go Back Full Screen Close Quit

#### 19. First Idea

- Let us see if any of the above symmetric dependencies satisfy the desired property.
- Since for q, only scaling makes sense, we can only consider two possibilities: sc-sc and sh-sc.
- Let us consider them one by one.
- In the sc-sc case, we have  $q(t) = A \cdot t^a$ .
- Since we want a non-negative value, we have A > 0.
- Since we want q(t) to be increasing with time, we have to take a > 0.
- However, in this case:
  - -q(0) is zero while we want it to be positive, and
  - -q(t) tends to infinity as t increases while we want it to tend to some constant.

Full Screen

Close

#### 20. First Idea: sh-sc Case

- In the sh-sc case, we have  $q(t) = A \cdot \exp(a \cdot t)$ .
- Again, since we want a non-negative value, we have to take A > 0.
- Since we want q(t) to be increasing with time, we have to take a > 0; in this case:
  - -q(0) is positive, which is exactly what we wanted,
  - however, q(t) tends to infinity as t increases while we want it to tend to some constant.

Natural Symmetries Scaling-to-Scaling (sc-sc) Shift-to-Scaling (sh-sc) Scaling-to-Shift (sc-sh) Shift-to-Shift (sh-sh) What Are Possible . . . First Idea So What Do We Do? Home Page Title Page **>>** Page 21 of 28 Go Back Full Screen Close Quit

#### 21. So What Do We Do?

- The first idea does not work, so what should we do?
- The above arguments about possible dependencies deal with the case when y directly depend on time t.
- However, in our case, cracks and potholes do not directly depend on time.
- What changes with time is stress, which, in its turn, causes the pavement to crack.
- In other words, instead of the direct dependence of the quantity q on time:
  - we have q depending on some auxiliary quantity z, and
  - we have z depending on time t.

Natural Symmetries Scaling-to-Scaling (sc-sc) Shift-to-Scaling (sh-sc) Scaling-to-Shift (sc-sh) Shift-to-Shift (sh-sh) What Are Possible . . . First Idea So What Do We Do? Home Page Title Page **>>** Page 22 of 28 Go Back Full Screen Close Quit

## So What Do We Do (cont-d)

- For both dependencies q(z) and z(t) we can have symmetrymotivated formulas.
- Let us see which combinations of these formulas provide the desired properties of q(t) = q(z(t)):
  - that this value is positive for t=0,
  - that this value increases for t > 0, and
  - that this value tends to a finite limit when  $t \to \infty$ .

# 23. Possible Options of the q(z) Dependence

- For q, only scaling is possible.
- $\bullet$  So, for possible dependencies q(z), we have:
  - either the sc-sc option  $q(z) = A \cdot z^a$
  - or the sh-sc option  $q(z) = A \cdot \exp(a \cdot z)$ .
- In the sc-sc option  $q(z) = A \cdot z^a$ , it does not make sense to consider sh-sc or sc-sc options for z(t); indeed:
  - as one can check, this will be equivalent to sh-sc or sc-sc symmetry for q(t),
  - and we have already shown that this is not possible.
- So, to go beyond previously considered options, we need to consider two remaining options for z(t):
  - sh-sh option  $z(t) = a_1 \cdot t + C_1$ , and
  - sc-sh option  $z(t) = a_1 \cdot \ln(t) + C_1$ .

## 24. Possible Options (cont-d)

- In the 1st case,  $q(t) = A \cdot z^a = A \cdot (a_1 \cdot t + C_1)^a$ , i.e.,  $q(t) = A_1 \cdot (t + c_2)^a$ , where  $A_1 = A \cdot (a_1)^a$  and  $c_2 = \frac{C_1}{a_1}$ .
- The need to have positive values of q implies A > 0, the need to have q(t) increasing leads to a > 0.
- However then, for  $t \to \infty$ , the resulting expression tends to infinity while we want it bounded.
- In the 2nd case,  $q(t) = A \cdot (a_1 \cdot \ln(t) + C_1)^a$ , i.e.,  $q(t) = A_1 \cdot (\ln(t) + c_2)^a$ , with  $A_1 = A \cdot (a_1)^a$  and  $c_2 = \frac{C_1}{a_1}$ .
- The need to have positive values of q implies A > 0, the need to have q(t) increasing leads to a > 0.
- However then, for  $t \to \infty$ , the resulting expression also tends to infinity while we want it bounded.

## **25.** sh-sc Option $q(z) = A \cdot \exp(a \cdot z)$

- In this option, it does not make sense to consider sh-sh or sc-sh options for z(t); indeed:
  - as one can check, this will be equivalent to sh-sc or sc-sc symmetry for q(t),
  - and we have already shown that this is not possible.
- So, to go beyond previously considered options, we need to consider two remaining options for z(t):
  - sc-sc option  $z(t) = A_1 \cdot t^{a_1}$ , and
  - sh-sc option  $z(t) = A_1 \cdot \exp(a_1 \cdot t)$ .
- In the 1st case,  $q(t) = A \cdot \exp(a \cdot z) = A \cdot \exp((a \cdot A_1) \cdot t^{a_1})$ .
- The need to have positive values of q implies A > 0.
- The behavior of this expression depends on the sign of the product  $a \cdot A_1$ .

- If  $a \cdot A_1 > 0$ , then the need to have q(t) increasing leads to  $a_1 > 0$ .
- However then, for  $t \to \infty$ , the resulting expression tends to infinity and we want it bounded.
- If  $a \cdot A_1 < 0$ , then the need to have q(t) increasing leads to  $a_1 < 0$ .
- However then, for  $t \to 0$ , we have  $t^{-|a_1|} \to \infty$ , hence  $(a \cdot A_1) \cdot t^{-|a_1|} \to -\infty$ , and  $q(t) = A \cdot \exp((a \cdot A_1) \cdot t^{-|a_1|}) \to 0$ , but we want the value q(0) to be positive.
- So, the only possible case is the second case, when  $q(t) = A \cdot \exp(a \cdot z) = A \cdot ((a \cdot A_1) \cdot \exp(a_1 \cdot t)).$
- This is exactly the desired formulas.
- Thus, we have indeed justified the empirical dependencies.
